1 Preface

The CxQuery API Guide documents the Checkmarx Query Language (CxQL) used in CxAudit to query source code.

CxQL allows us to virtually data-mine any aspect of the source, and to build custom queries.

Checkmarx-provided queries are written using the CxQL.

These queries can be inherited, expanded, or rewritten.

Note: CxQL queries are language-dependent.

2 Introduction

A query written in Checkmarx Query Language allows us to analyze the scanned code and return a list of results.

Each result can be an element in the scanned code (e.g. a variable) or a “flow” – a path in the code consisting of an ordered list of these elements.

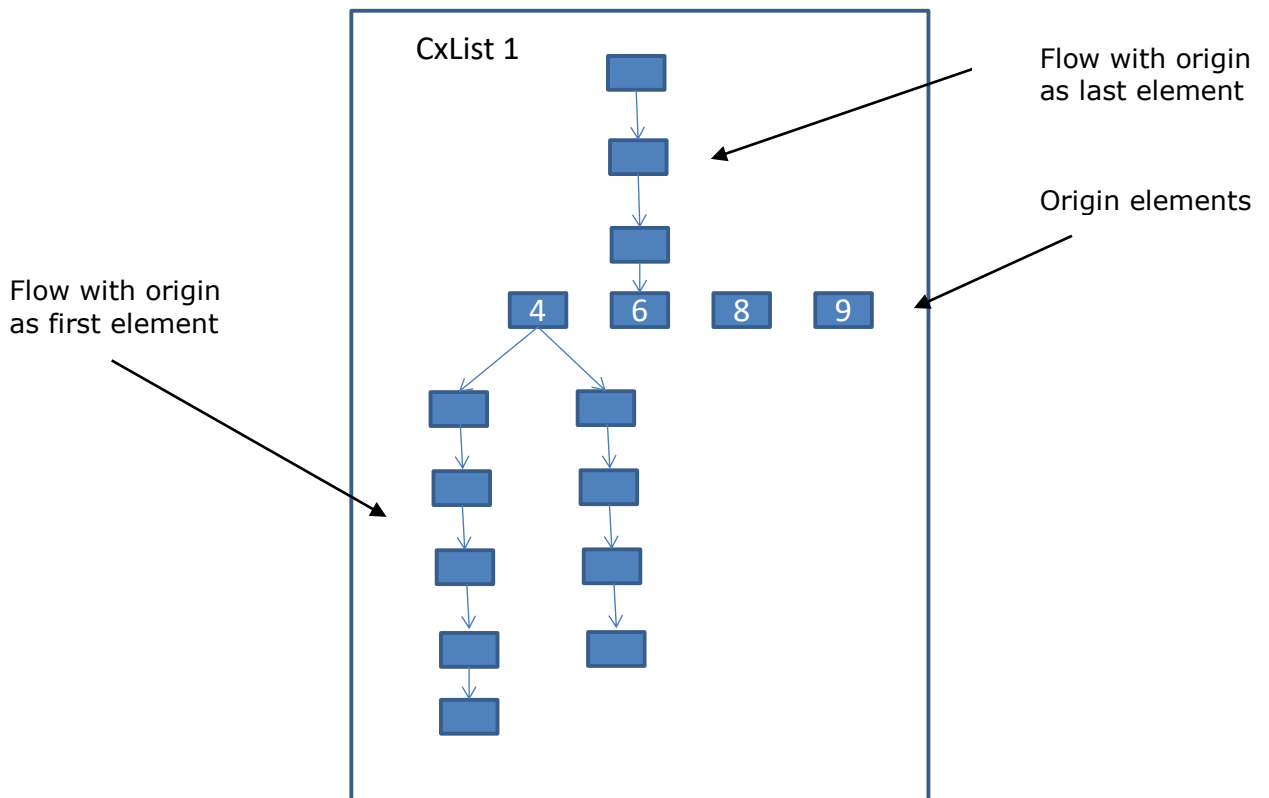

2.1 Definitions

Basic code element – Code elements such as variables, method invocations and assignments that have representation in the code model.

Data flow (flow) – an ordered list of code elements that represent a possible data change progression in the program from a certain location where the data has changed and the end location where that change had an affect (as a subsequent data change).

Every flow is attached to an origin basic code element. This origin element may be the first or last code element in the flow. The origin element appears as the first element in the flow if that element was queried as to whether it influenced other elements. The origin element appears as the last element in the flow if that element was queried as to whether it was influenced by other elements.

CxList - the central data type in CxQL. The CxList is a list that consists of basic code elements such as variables, method invocations, assignments, and so forth. Each element may have an attached flow, if the element was added to the CxList because it fulfilled a certain flow query.

There are two special CxList objects by default:

All – contains all elements in the scanned code, and

result – the return value of the query.

Notes:

- “All” contains only basic code elements (without any flow).
- To create a new empty CxList use All.NewCxList().

2.2 Queries and Commands:

Now we are ready for our first query:

CxQL

```
This example demonstrates the use of "All" and "result" objects
result = All;

This would return a list of all objects in the code for a specific language
```

CxList includes a vast assortment of commands. In the following example, we investigate the CxList FindByName command:

CxQL

```
result = All.FindByName("*MyName*")
This would return a list of all objects where their name
contains the string "MyName".

It is the same as:
CxList cm1 = All.FindByName("*MyName*");
result = cm1;
```

Because the return value of almost every command is also of type CxList, several commands can be executed consecutively as shown in the example below.

It is important to note that most CxList methods return a subset of the original CxList (we can think of the method as a **filter**).

So in the example below, consisting of chained method calls:

```
All.FindByName("*.MyName").FindByType (typeof(MemberAccess))
```

The order of execution is:

- 1 Return a CxList consisting of a subset of “All” (all elements in code) with name containing MyName .
- 2 Return a subset of the previous result , only those of type MemberAccess.

CxQL

```
result = All.FindByName("*.MyName").FindByType (typeof(MemberAccess));
This would return a list of all access data members in the code whose name
contains the string "MyName" (e.g. a = b.MyName ).
First we find all objects whose name ends with ".MyName", and on the result
we execute another command that retrieves only access members.
This is the same as the following:

result = All.FindByType (typeof(MemberAccess)).FindByName("*.MyName");
```

* The difference is in efficiency. We want to work on the smallest groups possible, so actually first looking by name and then by type should be more efficient.

While the result in both cases is identical (order of filtering doesn't matter), the choice of execution order can have a noticeable effect on performance.

2.2.1 Data Flow Graph

We have seen in the previous section several commands that can operate on CxList objects. All the commands were "static" since they locate elements in the code, but they do not capture the flow between elements. The Data Flow Graph (DFG) in Source Code Analysis (SCA) describes how data is flowed through the program. Object A is "data influenced by" object B if the value of B flows to A.

In the example below, **d** is "data influenced by" **a** and **b**, but not by **c**. This means that both **a** and **b** are "data influencing on" **d**, but not on **c**.

```
C#  
  
a = 5;  
b = 6;  
c = 7;  
d = a + b;
```

3 Using cxLog

The cxlog object is a way to output debug messages from within a query, in the CxAudit environment.

The messages can be seen in the CxAudit bottom window, in the tab named "Debug Messages".

The most common case is when exceptions happen, so that the exception details can be viewed after the query has finished.

For example:

```
CXQL
foreach (CxList rt in redirectThings)
{
    try
    {
        [...]
    }
    catch (Exception ex)
    {
        // in case of an exception in the loop
        cxLog.WriteDebugMessage(ex);
    }
}
```

It can also be used for more detailed inspection of the query behavior from within the query itself.

For example:

```
CXQL
if(hexEquiv != "")
{
    cxLog.WriteDebugMessage("hexEquiv=" + hexEquiv + ", #finds=" +
finds.Count);
    count++;
}
else
{
    cxLog.WriteDebugMessage("hexEquiv=empty" + hexEquiv + ", #finds=" +
finds.Count);
}
```

Note that `cxLog.WriteDebugMessage` cannot display CxList data directly. Executing that `cxLog.WriteDebugMessage(myCxList)` will yield just an integer value.

However, in many cases (when the CxList does not represent a path), one can retrieve and output the CxList element fields.

For example:

```
CXQL
CxList inputs = Find_Inputs();
foreach (CxList inp in inputs)
{
    CSharpGraph inp_Graph = inp.data.GetByIndex(0) as CSharpGraph;
    String inp_Name = inp_Graph.ShortName;
    cxLog.WriteDebugMessage("Name = " + inp_Name);
}
```

4 Methods Documentation

4.1 CxList.Add Method (int, IGraph)

Adds to the current instance the given graph node, indexed by the given id.

Syntax

```
CxQL
public void Add(int id, IGraph node)
```

Parameters

Id

Id of the node to be added to the graph node.

Node

Graph node to be associated to the given Id.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Example

```
CxQL

This example demonstrates the CxList.Add() method.
The input source code is:

int b, a = 5;
if (a == 33)
    b = 6;

CxList myList = All.FindByName("a");
CSharpGraph nodeGraph = All.FindByName("b").GetFirstGraph();
myList.Add(nodeGraph.NodeId, nodeGraph);
result = myList;

The resulting list will include the initial two "a"'s and the first b
```

4.2 CxList.Add Method (CxList)

Add all the elements from the given CxList to the current instance.

Syntax

```
CxQL  
public void Add(CxList list)
```

Parameters

list

The CxList to be added to the current CxList instance.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Example

```
CxQL  
  
This example demonstrates the CxList.Add() method.  
The input source code is:  
  
int b, a = 5;  
if (a == 33)  
    b = 6;  
  
CxList list_a = All.FindByName("a");  
CxList list_b = All.FindByName("b");  
list_a.Add(list_b);  
result = list_a;  
The resulting list will contain 4 elements
```

4.3 CxList.Add Method (KeyValuePair<int, IGraph>)

Add the given pair to the current CxList instance.

Syntax

```
CxQL
public void Add(KeyValuePair<int, IGraph> dictionary)
```

Parameters

dictionary

Pair to be added to the current CxList instance.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Example

```
CxQL

This example demonstrates the CxList.Add() method.
The input source code is:

int b, a = 5;
if (a == 33)
    b = 6;

CxList myList = All.FindByName("a");
foreach(KeyValuePair<int,IGraph> entry in All.FindByName("b"))
{
    myList.Add(entry);
}
result = myList;
The resulting list will contain 4 elements
```

4.4 CxList.CallingMethodOfAny Method (CxList)

Returns a CxList which is a subset of "this" instance and are methods or constructors declarations which matches the given CxList elements.

Syntax

```
CxQL  
public CxList CallingMethodOfAny(CxList elements)
```

Parameters

elements

The list of elements containing the methods or constructors to look for their declaration.

Return Value

The methods or constructor declarations which matches the given CxList elements.

Example

```
CxQL  
  
This example demonstrates the CxList.CallingMethodOfAny() method.  
The input source code is:  
void foo()  
{  
    int goo = 3;  
    int boo = 5;  
}  
  
result = All.CallingMethodOfAny(All.FindByName ("oo"));  
  
The result would consist of 1 item:  
foo (in void foo())
```

4.5 CxList.Clear Method ()

Clears the information in “this” instance.

Syntax

```
CxQL  
public bool Clear()
```

Parameters

None

Return Value

None

Comments

This method removes all the information stored in the List.

Example

```
CxQL  
  
This example demonstrates the CxList.Clear() method.  
  
CxList myList = All;  
MessageBox.Show(myList.Count.ToString());  
  
myList.Clear();  
MessageBox.Show(myList.Count.ToString());
```

4.6 CxList Concatenate Methods

4.6.1 CxList.Concatenate Method (CxList list, bool _testFlow)

Concatenates two nodes into a flow.

Syntax

```
CxQL
public CxList Concatenate (CxList list, bool _testFlow)
```

Parameters

list

A CxList containing one node only. This node will be concatenated to **this** instance

_testFlow

If true, searches for a flow between **this** instance and **list**. Otherwise, connects the two nodes directly (more efficient).

Return Value

A flow that starts with **this** instance node, and ends with the **list** parameter node.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. If either **this** instance or **list** parameter contains more than one node or contains flows, the function return value is undefined.
2. This function is deprecated, use **ConcatenatePath** instead.

Example

The following code example shows how you can use the Concatenate method.

```
CxQL

void main()
{
    int a = 1;
    int b = 2;
    int c = a + b;
    printf("%d", c);
}

CxList one = All.FindByName("1");
CxList two = All.FindByName("2");
result = one.Concatenate(two);

the result would be -
1 flow found:
[1] -> [2]
```

Version Information

Supported from v7.1.2

4.6.2 CxList.Concatenate Method (CxList list)

Concatenates two nodes into a flow.

Syntax

```
CxQL  
public CxList Concatenate (CxList list)
```

Parameters

list

A CxList containing one node only. This node will be concatenated to **this** instance

Return Value

A flow that starts with **this** instance node, and ends with the **list** parameter node.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. This function calls CxList.Concatenate(list, false).
2. If either this instance or list parameter contains more than one node or contains flows, the function return value is undefined.
3. This function is deprecated, use ConcatenatePath instead.

Version Information

Supported from v7.1.2

4.6.3 CxList.ConcatenatePath Method (CxList list, bool _testFlow)

Concatenates two flows into one connected flow.

Syntax

```
CxQL  
public CxList ConcatenatePath (CxList list, bool _testFlow)
```

Parameters

list

A CxList containing one flow only. This flow will be concatenated to **this** instance

_testFlow

If true, searches for a flow between **this** instance and **list**. Otherwise, connects the two flows directly (more efficient).

Return Value

A flow that starts with **this** instance flow, and ends with the **list** parameter flow.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

Both **this** instance and **list** have to contain only one flow (or one node as a private case), otherwise return value is undefined.

Example

The following code example shows how you can use the ConcatenatePath method.

```
CxQL

void main()
{
    int a = 1;
    int b = 2;
}

CxList one = All.FindByName("1");
CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
//Declarator is a new type defined in cXQL
CxList flow1 = a.InfluencedBy(one); // [1] -> [a]

CxList two = All.FindByName("2");
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList flow2 = b.InfluencedBy(two); // [2] -> [b]

result = flow2.ConcatenatePath(flow1);

the result would be -
1 flow found:
[2] -> [b] -> [1] -> [a]
```

Version Information

Supported from v7.1.2

4.6.4 CxList.ConcatenatePath Method (CxList list)

Concatenates two flows into one connected flow.

Syntax

```
CxQL
public CxList ConcatenatePath (CxList list)
```

Parameters

list

A CxList containing one flow only. This flow will be concatenated to **this** instance

Return Value

A flow that starts with **this** instance flow, and ends with the **list** parameter flow.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. This function calls CxList.ConcatenatePath(list, true).

- Both this instance and list have to contain only one flow (or one node as a private case), otherwise return value is undefined.

Version Information

Supported from v7.1.2

4.6.5 CxList.ConcatenateAllPaths Method (CxList list, bool _testFlow)

Concatenates all flows in this instance to all flows in **list**.

Syntax

```
CxQL
public CxList ConcatenateAllPaths (CxList list, bool _testFlow)
```

Parameters

list

A CxList containing flows. These flow will be concatenated to the flows in **this** instance

_testFlow

If true, searches for a flow between **this** instance and **list**. Otherwise, connects the two flows directly (more efficient).

Return Value

A product of all flows in **this** instance with the ones in **list** parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

If **this** instance contains *n* flows in it and **list** contains *m* flows in it, the return set will contain *nxm* flows, where each flow from **this** instance will be concatenated to each flow from **list**.

Example

The following code example shows how you can use the ConcatenateAllPaths method.

```
CxQL

void main()
{
    int a = 1;
    int b = 2;
}

CxList one = All.FindByName("1");
CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
CxList flow1 = a.InfluencedBy(one); // [1] -> [a]
CxList two = All.FindByName("2");
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList flow2 = b.InfluencedBy(two); // [2] -> [b]
CxList flow = flow1 + flow2;
result = flow.ConcatenateAllPaths(flow);
the result would be -
4 flow found:
[1] -> [a] -> [1] -> [a]
```

```
[1] -> [a] -> [2] -> [b]
[2] -> [b] -> [1] -> [a]
[2] -> [b] -> [2] -> [b]
```

Version Information

Supported from v7.1.2

4.6.6 CxList.ConcatenateAllPaths Method (CxList list)

Concatenates all flows in this instance to all flows in **list**.

Syntax

```
CxQL
public CxList ConcatenateAllPaths (CxList list)
```

Parameters

list

A CxList containing flows. These flow will be concatenated to the flows in **this** instance

Return Value

A product of all flows in **this** instance with the ones in **list** parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. This function calls CxList.ConcatenateAllPaths(list, true).
2. If this instance contains n flows in it and list contains m flows in it, the return set will contain $n \times m$ flows, where each flow from this instance will be concatenated to each flow from list.

Version Information

Supported from v7.1.2

4.6.7 CxList.ConcatenateAllSources Method (CxList list)

Concatenates the node in **list** to each node in **this** instance. Concatenation is node-to-node (doesn't support connecting flows).

Note: Currently is identical to calling ConcatenateAllSources with testFlow = false

Syntax

```
CxQL
public CxList ConcatenateAllSources (CxList list)
```

Parameters

list

A CxList. It will be concatenated to each node in this instance

Return Value

Flows that starts with **this** instance nodes, and end with the **list** parameter node.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. If the **list** parameter contains more than one node or contains flows or **this** instance contains flows, the function return value is undefined.
2. The number of the returned items is same as the number of items in **this** instance.
3. This function calls the Concatenate function for each item in **this** instance with **list** as parameter.
4. Currently is identical to calling ConcatenateAllSources with testFlow = false

Example

The following code example shows how you can use the ConcatenateAllSources method.

```
CxQL

void main()
{
    int a = 1;
    int b = 2;
}

CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList main = All.FindByShortName("main");
CxList list = a + b;
result = list.ConcatenateAllSources(main);

the result would be -
2 flow found:
[a] -> [main]
[b] -> [main]
```

Version Information

Supported from v7.1.2

4.6.8 CxList.ConcatenateAllSources Method (CxList list, bool testFlow)

Concatenates the node in **list** to each node in **this** instance. Concatenation is node-to-node (doesn't support connecting flows).

Syntax

```
CxQL
public CxList ConcatenateAllSources (CxList list, bool testFlow)
```

Parameters

list

A CxList. It will be concatenated to each node in this instance

testFlow

If this parameter true -> test possible flow , otherwise connect directly

Return Value

Flows that starts with **this** instance nodes, and end with the **list** parameter node.

Exceptions

Exception type	Condition
----------------	-----------

[ArgumentNullException](#)
parameter is a null reference

Remarks

1. If the **list** parameter contains more than one node or contains flows or **this** instance contains flows, the function return value is undefined.
2. The number of the returned items is same as the number of items in **this** instance.
3. This function calls the Concatenate function for each item in **this** instance with **list** as parameter.

Example

The following code example shows how you can use the ConcatenateAllSources method.

CxQL

```
void main()
{
    int a = 1;
    int b = 2;
}

CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList main = All.FindByShortName("main");
CxList list = a + b;
result = list.ConcatenateAllSources(main, false);

the result would be -
2 flow found:
[a] -> [main]
[b] -> [main]
```

Version Information

Supported from v7.1.2

4.6.9 CxList.ConcatenateAllTargets Method (CxList list)

Concatenates each node in the **list** to the node in **this** instance. Concatenation is node-to-node (doesn't support connecting flows).

Syntax

CxQL

```
public CxList ConcatenateAllTargets (CxList list)
```

Parameters

list

A CxList. It will be concatenated to each node in this instance

Return Value

Flows that start with this instance nodes, and end with the **list** parameter node

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

1. If the "**this**" instance parameter contains more than one node or contains flows or **list** contains flows, the function return value is undefined.
2. The number of the returned items is same as the number of items in **list**.
3. This function calls the Concatenate function for **this** instance with each item in **list** as parameter..
4. Currently is identical to calling ConcatenateAllTargets with testFlow = false

Example

The following code example shows how you can use the ConcatenateAllSources method.

```
CxQL

void main()
{
    int a = 1;
    int b = 2;
}

CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList main = All.FindByShortName("main");
CxList list = a + b;
result = main.ConcatenateAllTargets(list);

the result would be -
2 flow found:
    [main] -> [a]
    [main] -> [b]
```

Version Information

Supported from v7.1.2

4.6.10 CxList.ConcatenateAllTargets Method (CxList list, bool testFlow)

Concatenates each node in the **list** to the node in **this** instance. Concatenation is node-to-node (doesn't support connecting flows).

Syntax

```
CxQL
public CxList ConcatenateAllTargets (CxList list, bool testFlow)
```

Parameters

list

A CxList. It will be concatenated to each node in this instance

testFlow

If this parameter true -> test possible flow , otherwise connect directly

Return Value

Flows that start with this instance nodes, and end with the **list** parameter node

Exceptions

Exception type	Condition
----------------	-----------

[ArgumentNullException](#)**parameter is a null reference**

Remarks

1. If the "**this**" instance parameter contains more than one node or contains flows or **list** contains flows, the function return value is undefined.
2. The number of the returned items is same as the number of items in **list**.
3. This function calls the Concatenate function for **this** instance with each item in **list** as parameter..

Example

The following code example shows how you can use the ConcatenateAllSources method.

CxQL

```
void main()
{
    int a = 1;
    int b = 2;
}

CxList a = All.FindByShortName("a").FindByType(typeof(Declarator));
CxList b = All.FindByShortName("b").FindByType(typeof(Declarator));
CxList main = All.FindByShortName("main");
CxList list = a + b;
result = main.ConcatenateAllTargets(list, false);

the result would be -
  2 flow found:
    [main] -> [a]
    [main] -> [b]
```

Version Information

Supported from v7.1.2

4.7 CxList.Contained Method (CxList, GetStartEndNodesType)

Returns a subset of "this" instance whose elements are contained in the given list, filtered according to the given nodes type.

Syntax

```
CxQL  
public CxList Contained(CxList pathList, GetStartEndNodesType requestedType)
```

Parameters

pathList

The list where the method looks for the requested node type.

requestedType

An enum matching the relevant GetStartEndNodes types, which are:

EndNodesOnly, StartNodesOnly, StartAndEndNodes, AllNodes and AllButNotStartAndEnd

Return Value

A subset of "this" instance with elements from the requested nodes type.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.Contained() method.  
The input source code is:  
  
void foo()  
{  
    int b = 2, a = 5, c;  
    if (a > b)  
        b = 3;  
    c = b;  
}  
  
result =  
All.FindByShortName("b").Contained(All.InfluencedBy(All.FindById(50)),  
CxList.GetStartEndNodesType.AllNodes); //Id 50 is "3" in "b = 3;"  
  
The result would consist of 2 items:  
    b (from b = 3;)  
    b (from c = b;)
```

```
result =  
All.FindByShortName("a").Contained(All.InfluencedBy(All.FindById(50)),  
GetStartEndNodesType.EndNodesOnly); //Id 50 is "3" in "b = 3;"
```

The result would consist of 0 items

4.8 CxList.ExtractFromSOQL Method ()

Extracts the parameters of a SOQL statement into a dictionary.

Syntax

```
CxQL  
public Dictionary<String, List<String>> ExtractFromSOQL()
```

Return Value

A dictionary with keys that match SOQL keywords and their relevant parameters.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.ExtractFromSOQL() method.  
The input source code is:  
  
int b = 0;  
String a = "select * from table where x=" + b;  
  
Dictionary <String, List<String>> result = All.ExtractFromSOQL();  
  
the result would consist of 3 results:  
    { "select" : "*",  
      "from"   : "table",  
      "where"  : "x=" } }
```

4.9 CxList.ExtractFromSOQL Method (string)

Extracts the parameters of the given keyword from a SOQL statement into a list.

Syntax

```
CxQL  
public List<string> ExtractFromSOQL(string keyword)
```

Parameters

keyword

The SOQL keyword to extract.

Return Value

A list with the parameters of the keyword.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the ExtractFromSOQL method.

CXQL

```
This example demonstrates the CxList.ExtractFromSOQL() method.  
The input source code is:
```

```
int b = 0;  
String a = "select * from table where x=" + b;  
  
List <String> result = All.ExtractFromSOQL("select");  
  
the result would be -  
  1 item found:  
    ["*"]
```

4.10 CxList.DataInfluencedBy Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are data influenced by the CxList specified in parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- DataInfluencedBy(list, [InfluenceAlgorithmCalculation.OldAlgorithm](#))

Syntax

```
CxQL  
public CxList DataInfluencedBy(CxList influencing)
```

Parameters

influencing

CxList data-influencing on "this" instance.

Return Value

A subset of "this" instance data influenced by the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.DataInfluencedBy() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = a;  
  
CxList five = All.FindByName("5");  
result = All.DataInfluencedBy(five);  
  
the result would be -  
6 items found:  
    a (in a = 5),  
    a (in a > 3),  
    > (in a > 3),  
    a (in b = a),  
    = (in b = a),  
    b (in b = a)
```

4.11 CxList.DataInfluencedBy Method (CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of this instance and its elements are data influenced by the CxList specified in the first parameter using the influence algorithm specified in the second parameter.

Syntax

```
CxQL
public CxList DataInfluencedBy(CxList influencing,
InfluenceAlgorithmCalculation algorithm)
```

Parameters

influencing

CxList data-influencing on "this" instance.

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

[OldAlgorithm](#), [NewAlgorithm](#)

Return Value

A subset of "this" instance data influenced by the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CXQL

This example demonstrates the CxList.DataInfluencedBy() method.
The input source code is:
int b, a = 5;
if (a > 3)
    b = a;

CxList five = All.FindByName("5");
result = All.DataInfluencedBy(five,
CxList.InfluenceAlgorithmCalculation.NewAlgorithm);
the result would be -
    6 items found:
        a (in a = 5),
        a (in a > 3),
        > (in a > 3),
        a (in b = a),
        = (in b = a),
        b (in b = a)
```

4.12 CxList.DataInfluencingOn Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are data influencing on the CxList specified in parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- `DataInfluencingOn(list, InfluenceAlgorithmCalculation.OldAlgorithm)`

Syntax

```
CxQL  
public CxList DataInfluencingOn(CxList influenced)
```

Parameters

influenced

CxList data-influenced by "this" instance.

Return Value

A subset of "this" instance data influencing on the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.DataInfluencingOn() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = a;  
  
CxList b = All.FindByName("*.b");  
result = All.DataInfluencingOn(b);  
  
the result would be -  
3 items found:  
    a (in b = a),  
    a (in a = 5),  
    5 (in a = 5)
```

4.13 CxList.DataInfluencingOn Method (CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of "this" instance and its elements are data influencing on the CxList specified in the first parameter using the influence algorithm specified in the second parameter.

Syntax

```
CxQL
public CxList DataInfluencingOn(CxList influenced,
InfluenceAlgorithmCalculation algorithm)
```

Parameters

influenced

CxList data-influenced by "this" instance.

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

OldAlgorithm, NewAlgorithm

Return Value

A subset of "this" instance data influencing on the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CXQL

This example demonstrates the CxList.DataInfluencingOn() method.
The input source code is:

int b, a = 5;
if (a > 3)
    b = a;

CxList b = All.FindByName("*.b");
result = All.DataInfluencingOn(b,
    CxList.InfluenceAlgorithmCalculation.NewAlgorithm);

the result would be -
3 items found:
    a (in b = a),
    a (in a = 5),
    5 (in a = 5)
```

4.14 CxList.InfluencedBy Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are influenced (either data or control) by the CxList specified in parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- InfluencedBy(list, [InfluenceAlgorithmCalculation.OldAlgorithm](#))

Syntax

```
CxQL  
public CxList InfluencedBy(CxList influencing)
```

Parameters

influencing

CxList data-influencing on "this" instance.

Return Value

A subset of "this" instance influenced by (either data or control) the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CXQL  
This example demonstrates the CxList.InfluencedBy() method.  
Notice the difference between DataInfluencedBy and InfluencedBy  
The input source code is:  
int b = 2, a = 5, c;  
if (a > b)  
    b = 3;  
c = b;  
result = All.InfluencedBy(All.FindById(43)); // Id 43 is 5 from a = 5;  
Notice that among all the results also c (in c = b) appears because c is  
data-dependant on b=3, which in turn is control dependant on a > b, which  
itself is data-dependant on a = 5.  
  
result = All.DataInfluencedBy(All.FindById(43)); // 5  
Notice that now c (in c = b) doesn't appear because its value is not  
influenced by 5.
```

4.15 CxList.InfluencedBy Method

(CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of "this" instance and its elements are influenced (either data or control) by the CxList specified in the first parameter using the influence algorithm specified in the second parameter.

Syntax

```
CxQL
public CxList InfluencedBy(CxList influencing, InfluenceAlgorithmCalculation
algorithm)
```

Parameters

influencing

CxList data-influencing on "this" instance.

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

OldAlgorithm, NewAlgorithm

Return Value

A subset of "this" instance influenced by (either data or control) the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
This example demonstrates the CxList.InfluencedBy() method.
Notice the difference between DataInfluencedBy and InfluencedBy
The input source code is:
int b = 2, a = 5, c;
if (a > b)
    b = 3;
c = b;
result = All.InfluencedBy(All.FindById(43),
    CxList.InfluenceAlgorithmCalculation.NewAlgorithm); // Id 43 is 5
from a = 5;
Notice that among all the results also c (in c = b) appears because c is
data-dependant on b = 3, which in turn is control dependant on a > b,
which itself is data-dependant on a = 5.

result = All.DataInfluencedBy(All.FindById(43)); // 5
Notice that now c (in c = b) doesn't appear because its value is not
influenced by 5.
```

4.16 CxList.InfluencedByAndNotSanitized Method (CxList, CxList)

Returns a CxList which is a subset of "this" instance and its elements are influenced by the CxList specified in the first parameter, and their influencing path doesn't contain elements from the CxList specified in the second parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- `InfluencedByAndNotSanitized(influencing, sanitized, InfluenceAlgorithmCalculation.OldAlgorithm)`

Syntax

```
CxQL
public CxList InfluencedByAndnotSanitized(CxList influencing, CxList
sanitization)
```

Parameters

Influencing

CxList influencing on "this" instance.

sanitization

CxList that "cuts" the influencing path.

Return Value

A subset of "this" instance and its elements are influenced by the first specified parameter, and their influencing path doesn't contain element from the second CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
This example demonstrates the CxList.InfluencedByAndNotSanitized()
method.
The input source code is:

    string s = input();
    string s1 = fixSql(s);
    string s2 = s + s1;

    execute(s);      (*)
    execute(s1);
    execute(s2);    (*)

    s = s1;
    execute(s);
    execute(s1);
```

```
execute(s2);      (*)

s2 = s;
execute(s);
execute(s1);
execute(s2);

CxList execute = All.FindByName("execute");
CxList input = All.FindByName("input");
CxList fixSql = All.FindByName("fixSql");
result = execute.InfluencedByAndNotSanitized(input, fixSql);

Notice that only the lines marked with a (*) are returned. These are the
only statements that have an influencing path from the input() command,
without being completely sanitized by fixSql().
```

4.17 CxList.InfluencedByAndNotSanitized Method (CxList, CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of "this" instance and its elements are influenced by the CxList specified in the first parameter, and their influencing path doesn't contain elements from the CxList specified in the second parameter, using the influence algorithm specified in the third parameter.

Syntax

```
CxQL
public CxList InfluencedByAndnotSanitized(CxList influencing, CxList
sanitization, InfluenceAlgorithmCalculation algorithm)
```

Parameters

influencing

CxList influencing on "this" instance.

sanitization

CxList that "cuts" the influencing path.

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

[OldAlgorithm](#), [NewAlgorithm](#)

Return Value

A subset of "this" instance and its elements are influenced by the first specified parameter, and their influencing path doesn't contain element from the second CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
This example demonstrates the CxList.InfluencedByAndNotSanitized()
method.
The input source code is:

    string s = input();
    string s1 = fixSql(s);
    string s2 = s + s1;

    execute(s);      (*)
    execute(s1);
    execute(s2);    (*)

    s = s1;
```

```
execute(s);  
execute(s1);  
execute(s2);      (*)  
  
s2 = s;  
execute(s);  
execute(s1);  
execute(s2);
```

```
CxList execute = All.FindByName("execute");  
CxList input = All.FindByName("input");  
CxList fixSql = All.FindByName("fixSql");  
result = execute.InfluencedByAndNotSanitized(input, fixSql,  
    CxList.InfluenceAlgorithmCalculation.NewAlgorithm);
```

Notice that only the lines marked with a (*) are returned. These are the only statements that have an influencing path from the input() command, without being completely sanitized by fixSql().

4.18 CxList.InfluencingOn Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are influencing (data and control) on the CxList specified in parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- `InfluencingOn(influenced, InfluenceAlgorithmCalculation.OldAlgorithm)`

Syntax

```
CxQL  
public CxList InfluencingOn (CxList influenced)
```

Parameters

influenced

CxList influenced by "this" instance.

Return Value

A subset of "this" instance influencing on the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.InfluencingOn() method.  
The input source code is:  
  
int a;  
a = 5;  
b = a;  
  
CxList b_var = All.FindByShortName("b");  
result = All.InfluencingOn(b_var);  
  
the result would be -  
3 items found:  
    5,  
    a,  
    a
```

Version Information

CxAudit

Supported from v1.8.1

4.19 CxList.InfluencingOn Method

(CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of "this" instance and its elements are influencing (data and control) on the CxList specified in the first parameter using the influence algorithm specified in the second parameter.

Syntax

```
CxQL  
public CxList InfluencingOn (CxList influenced,  
InfluenceAlgorithmCalculation algorithm)
```

Parameters

influenced

CxList influenced by "this" instance.

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

OldAlgorithm, NewAlgorithm

Return Value

A subset of "this" instance influencing on the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.InfluencingOn() method.  
The input source code is:  
  
int a;  
a = 5;  
b = a;  
  
CxList b_var = All.FindByShortName("b");  
result = All.InfluencingOn(b_var,  
CxList.InfluenceAlgorithmCalculation.NewAlgorithm);  
  
the result would be -  
3 items found:  
5,  
a,  
a
```

4.20 CxList.InfluencingOnAndNotSanitized Method (CxList, CxList)

Returns a CxList which is a subset of "this" instance and its elements are influencing on (Data or Control), and an influencing path exists which doesn't contain elements from the sanitization.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- `InfluencingOnAndNotSanitized(list, InfluenceAlgorithmCalculation.OldAlgorithm)`

Syntax

```
CxQL
public CxList InfluencingOnAndNotSanitized (CxList influencing, CxList
sanitization)
```

Parameters

influencing

CxList influencing on "this" instance.

sanitization

CxList that "cuts" the influencing path

Return Value

A subset of "this" instance and its elements are influencing on the first specified parameter, and their influencing path doesn't contain elements from the CxList specified in second parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
This example demonstrates the CxList.InfluencingOnandNotSanitized()
method.
The input source code is:
    string s = input();
    string s1 = fixSql(s);
    string s2 = s + s1;

    execute(s);      (*)
    execute(s1);
    execute(s2);    (*)

    s = s1;
    execute(s);
    execute(s1);
    execute(s2);    (*)

    s2 = s;
```

```
execute(s);  
execute(s1);  
execute(s2);  
CxList execute = All.FindByName("execute");  
CxList input = All.FindByName("input");  
CxList fixSql = All.FindByName("fixSql");  
result = input.InfluencingOnAndNotSanitized(execute, fixSql);  
  
Notice that only the first line is returned (string s = input();)
```

4.21 CxList.InfluencingOnAndNotSanitized Method (CxList, CxList, InfluenceAlgorithmCalculation)

Returns a CxList which is a subset of "this" instance and its elements are influencing on (Data or Control), and an influencing path exists which doesn't contain elements from the sanitization using the influence algorithm specified in the third parameter.

Syntax

```
CxQL  
public CxList InfluencingOnAndNotSanitized (CxList influencing, CxList  
sanitization, InfluenceAlgorithmCalculation algorithm)
```

Parameters

influencing

CxList influencing on this instance.

sanitization

CxList that "cuts" the influencing path

algorithm

An enum matching the relevant InfluenceAlgorithmCalculation options which are:

OldAlgorithm, NewAlgorithm

Return Value

A subset of "this" instance and its elements are influencing on the first specified parameter, and their influencing path doesn't contain elements from the CxList specified in the second parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
This example demonstrates the CxList.InfluencingOnandNotSanitized()  
method.  
The input source code is:  
    string s = input();  
    string s1 = fixSql(s);  
    string s2 = s + s1;  
  
    execute(s);      (*)  
    execute(s1);  
    execute(s2);    (*)  
  
    s = s1;
```

```
execute(s);
execute(s1);
execute(s2);      (*)

s2 = s;
execute(s);
execute(s1);
execute(s2);
CxList execute = All.FindByName("execute");
CxList input = All.FindByName("input");
CxList fixSql = All.FindByName("fixSql");
result = input.InfluencingOnAndNotSanitized(execute, fixSql,
      CxList.InfluenceAlgorithmCalculation.NewAlgorithm);

Notice that only the first line is returned (string s = input();)
```

4.22 CxList.NotInfluencedBy Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are not influenced (either data or control) by the CxList specified in parameter.

Syntax

```
CxQL  
public CxList NotInfluencedBy(CxList influencing)
```

Parameters

influencing

CxList data on "this" instance.

Return Value

A subset of "this" instance not influenced by (either data or control) the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
This example demonstrates the CxList.NotInfluencedBy() method.  
  
The input source code is:  
int b = 2, a = 5, c;  
if (a > b)  
    b = 3;  
c = b;  
  
result = All.NotInfluencedBy(All.FindById(43)); // 5  
Returns every object besides a and 5 (from a = 5) and a (from a > b)  
Notice that among all the results also b (in b = 2) appears because it does  
not influence the value of a.
```

4.23 CxList.NotInfluencingOn Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are not influencing (data and control) on the CxList specified in parameter.

Syntax

```
CxQL  
public CxList NotInfluencingOn (CxList notInfluenced)
```

Parameters

notInfluenced

CxList data in "this" instance.

Return Value

A subset of "this" instance not influencing on the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.NotInfluencingOn() method.  
The input source code is:  
  
int a, c = 3;  
a = 5;  
b = a;  
  
CxList b_var = All.FindByShortName("b");  
result = All.NotInfluencingOn(b_var);  
  
the result would be -  
  2 items found:  
    c,  
    3
```

4.24 CxList.FindAllMembers Method (CxList)

Returns a CxList which is a subset of “this” instance, with elements that are members of the classes in the given CxList.

Syntax

```
CxQL  
public CxList FindAllMembers(CxList Ids)
```

Parameters

Ids

The list of Classes whose members are to be found.

Return Value

A subset of “this” instance, with elements that are members of the classes in the given CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.FindAllMembers() method.  
The input source code is:  
  
public class MyClass  
{  
    public int b, a = 5;  
    boolean c=false;  
}  
result = All.FindAllMembers(All.FindByName("MyClass"));  
The result would consist of 3 items:  
    b (public int b, a = 5;),  
    a (public int b, a = 5;),  
    c (boolean c=false)
```

4.25 CxList.FindAllReferences Method (CxList)

Returns a CxList which is a subset of "this" instance, with elements that are references of the given CxList.

Syntax

```
CxQL  
public CxList FindAllReferences(CxList referenced)
```

Parameters

referenced

The CxList whose references are to be found.

Return Value

A subset of "this" instance, with elements that are references of the given CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindAllReferences() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = a;  
  
result = All.FindAllReferences(All.FindById(36)); //a in (a = 5)  
  
the result would consist of 3 items:  
    a (in a = 5),  
    a (in a > 5),  
    a (in b = a)
```

4.26 CxList.FindAllReferences Method (CxList, CxList)

Returns a CxList which is a subset of "this" instance, with elements that are references of the given CxList, excluding elements in the second CxList.

Syntax

```
CxQL  
public CxList FindAllReferences(CxList referenced, CxList exclude)
```

Parameters

referenced

The CxList whose references are to be found.

exclude

The CxList whose elements will be ignored and excluded.

Return Value

A subset of "this" instance, with elements that are references of the given CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindAllReferences() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = a;  
  
result = All.FindAllReferences(All.FindById(36), All.FindById(30)); //a in  
(a = 5), b in (int b)  
  
the result would consist of 3 items:  
    a (in a = 5),  
    a (in a > 5),  
    a (in b = a)
```

4.27 CxList.FindByAssignmentSide Method (AssignmentSide)

Returns a CxList which is a subset of "this" instance and its elements are being on the given side of an assignment expression.

Syntax

```
CxQL  
public CxList FindByAssignmentSide(CxList.AssignmentSide side)
```

Parameters

side

The side of the assignment expression, which can be one of the following values: [Left](#), [Right](#) (see Section [AssignmentSide](#)).

Return Value

A subset of "this" instance on the specified side of an assignment expression.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByAssignmentSide() method.  
The input source code is:  
  
a = 3;  
b = a;  
if (a == 4)  
    b = a - 1;  
  
result = All.FindByAssignmentSide(CxList.AssignmentSide.Left);  
  
The result would consist of 3 items:  
    a (in a = 3),  
    b (in b = a),  
    b (in b = a - 1)
```

Version Information

Supported from v1.8.1

4.28 CxList.FindByCustomAttribute Method (string)

Returns a CxList which is a subset of "this" instance and its elements are custom attributes of the specified name.

Syntax

```
CxQL  
public CxList FindByCustomAttribute(string name)
```

Parameters

name

The attribute name.

Return Value

A subset of "this" instance with custom attributes of the specified name.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.FindByCustomAttribute() method.  
The input source code is:  
  
[WebMethod]  
void foo()  
{  
  
}  
  
result = All. FindByCustomAttribute("WebMethod");  
  
the result would consist of 1 item:  
    foo
```

4.29 CxList.FindByExtendedType Method (string)

Returns a CxList which is a subset of "this" instance and the type of its elements match the type specified as parameter.

Syntax

```
CxQL  
public CxList FindByExtendedType (string extendedType)
```

Parameters

extendedType

The extended type of the objects to be found. Prefix and postfix wildcard (*) are supported.

Return Value

A subset of "this" instance and its elements are those with type specified by the parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.FindByExtendedType() method.  
The input source code is:  
  
MyClass a;  
MyClassExtended b;  
int c;  
a.DataMember = 3;  
c = a.Method();  
  
result = All.FindByExtendedType ("MyClass*");  
the result would consists of 4 items:  
    a (in MyClass a)  
    b (in MyClassExtended b)  
    a (in a.DataMember = 3)  
    a (in c = a.Method())
```

4.30 CxList.FindByFathers Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are those that their CxDOM-Fathers are in the specified CxList.

Syntax

```
CxQL  
public CxList FindByFathers(CxList fathers)
```

Parameters

fathers

A CxList consisting of the Fathers to be matched.

Return Value

A subset of "this" instance and its elements are those which their CxDOM-Fathers are in the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
This example demonstrates the CxList.FindByFathers() method.  
First we find the number "3", then we seek for 3's fathers (which are  
the assignment expressions), finally we look for the  
assignment-expressions' sons (the "a", "b" and the "3"s)  
Input source code is:  
  
a = 3;  
b = a;  
if (a == 4)  
    b = a - 1;  
CxList three = All.FindByName("*.3");  
CxList threesFathers = three.GetFathers();  
Result = All.FindByFathers(threesFathers);  
the result would be -  
4 items found:  
    a (in a = 3),  
    3 (in a = 3),  
    b (in b = 3),  
    3 (in b = 3)
```

4.31 CxList.FindByFieldAttributes Method (Modifiers)

Returns a CxList which is a subset of "this" instance and its elements are modified by the modifier (private, external, etc).

Syntax

```
CxQL  
public CxList FindByFieldAttributes(Modifiers attrib)
```

Parameters

Attrib

Attribute of the fields to be found.

Return Value

A subset of "this" instance and its elements are those with attribute attrib.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByAttributes() method.  
Input source code is:  
public class c11{  
    private void foo(){  
    protected void guu(){  
    private int a,b;  
    protected int c;  
}  
  
result=All.FindByFieldAttributes(Modifiers.Protected);  
the result would be -  
2 items found:  
    guu (in protected void guu(){}),  
    c (int c;)
```

Version Information

Supported from **CxAuditv2.0.5**

4.32 CxList.FindByFileName Method (string)

Returns a CxList which is a subset of "this" instance and its elements are in a given source code file.

Syntax

```
CxQL  
public CxList FindByFileName(string FileName)
```

Parameters

FileName

String with the file name.

Return Value

A subset of "this" instance with elements from a given file name.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByFileName() method.  
The input source code is:  
  
//file myCode.cs  
class C1 {  
    void foo() {  
        int i;  
    }  
}  
  
result = All.FindByFileName("*myCode.cs");  
  
the result consists of 5 items:  
    C1  
    void,  
    foo,  
    int,  
    i
```

Version Information

Supported from v1.8.1

4.33 CxList.FindById Method (int)

Finds all objects with the specified id. This method is mainly used to find all the uses of a code element (e.g. variable, class).

Syntax

```
CxQL  
public CxList FindById (int id)
```

Parameters

id

id number to be found.

Return Value

A subset of "this" instance and its elements that have the specified id number.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindById() method.  
The input source code is:  
  
a = 3;  
b = a;  
if (a == 4)  
    b = a - 1;  
  
result = All.FindById(60);  
  
the result would be -  
1 item found:  
    b (in b = a - 1)
```

4.34 CxList.FindByInitialization Method (CxList)

Returns a CxList which is a subset of "this" instance and contains elements initialized by the given CxList.

Syntax

```
CxQL  
public CxList FindByInitialization(CxList initializers)
```

Parameters

initializers

A CxList with initializers to search in "this" instance.

Return Value

A subset of "this" instance containing declarators initialized by the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByInitialization() method.  
The input source code is:  
  
int b = 5;  
  
CxList declarators = All.FindByType(typeof(Declarator));  
result= declarators.FindByInitialization(All);  
  
the result would consist of 1 item:  
    b
```

Version Information

Supported from v1.8.1

4.35 CxList.FindByLanguage Method (string)

Returns a CxList which is a subset of "this" instance whose elements are from the given language.

Syntax

```
CxQL  
public CxList FindByLanguage (string languageName)
```

Parameters

languageName

Language name to search.

Return Value

A subset of "this" instance whose elements are from the given language.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByLanguage() method.  
The input source code is:  
//file myCode.cs  
class myCode {  
  
}  
  
//file MyCode.java  
class MyCode {  
  
}  
  
result = All.FindByLanguage ("Java");  
the result would consist of 1 item:  
myCode (class MyCode)
```

4.36 CxList.FindByMemberAccess

Method (string)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. Notice that this is a case-sensitive search. For a non case-sensitive search, please use the FindByMemberAccess Method (string, bool) instead.

Syntax

```
CxQL  
public CxList FindByMemberAccess(string memberAccess)
```

Parameters

memberAccess

Contains both the name of the type and the name of the accessed member in the qualified notation (eg. "CheckBoxList.SelectedValue"). Prefix and suffix wild card (*) are permitted.

Return Value

A subset of "this" instance where its elements are the ones which their given member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByMemberAccess() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
result = All.FindByMemberAccess("MyClass.DataMember");  
the result would consist of 1 item:  
    a.DataMember (in a.DataMember = 3)  
  
result = All.FindByMemberAccess("MyClass.Met*");  
  
the result would consist of 1 item:  
    a.Method (in b = a.Method())
```

4.37 CxList.FindByMemberAccess

Method (string,bool)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. This search allows both case-sensitive and non case-sensitive searches.

Syntax

```
CxQL  
public CxList FindByMemberAccess(string memberAccess, bool caseSensitive)
```

Parameters

memberAccess

Contains both the name of the type and the name of the accessed member in qualified notation (eg. "CheckBoxList.SelectedValue"). Prefix and suffix wild card (*) are permitted.

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByMemberAccess() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
result = All.FindByMemberAccess("MyClass.dataMember", true);  
Notice that the result would consist of 0 items because the search is case-sensitive.  
  
result = All.FindByMemberAccess("MyClass.dataMember", false);  
The result would consist of 1 item:  
    a.DataMember (in a.DataMember = 3)  
  
result = All.FindByMemberAccess("MyClass.met*", true);  
Notice that the result would consist of 0 items because the search is case-sensitive.  
  
result = All.FindByMemberAccess("MyClass.met*", false);
```

```
the result would consist of 1 item:  
a.Method (in b = a.Method())
```

Version Information

Supported from v1.8.1

4.38 CxList.FindByMemberAccess

Method (string,string)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. This is a case-sensitive search by both the name of the type and the name of the accessed member. For a non case-sensitive search please use the `FindByMemberAccess Method(string, string, bool)` instead.

Syntax

```
CxQL
public CxList FindByMemberAccess(string typeName, string memberName)
```

Parameters

typeName

Contains the name of the accessed type (eg. "CheckBoxList");

memberName

Contains the name of the accessed member (eg. "SelectedValue");

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByMemberAccess() method.
The input source code is:
MyClass a;
int b;
a.DataMember = 3;
b = a.Method();
result = All.FindByMemberAccess("MyClass", "DataMember");

The result would consist of 1 item:
    a.DataMember (in a.DataMember = 3)

result = All.FindByMemberAccess("MyClass", "Met*");

The result would consist of 1 item:
    a.Method (in b = a.DataMethod())
```

Version Information

Supported from v7.9.0

4.39 CxList.FindByMemberAccess

Method (string, string, bool)

Returns a CxList which is a subset of this instance where its elements are the ones that match the given member being accessed. This search allows both case-sensitive and non case-sensitive searches by the type name and the name of the accessed member.

Syntax

```
CxQL
public CxList FindByMemberAccess(string typeName, string memberName, bool
caseSensitive)
```

Parameters

typeName

Contains the name of the accessed type (eg. "CheckBoxList");

memberName

Contains the name of the accessed member (eg. "SelectedValue");

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByMemberAccess() method.
The input source code is:
MyClass a;
int b;
a.DataMember = 3;
b = a.Method();
result = All.FindByMemberAccess("MyClass", "dataMember", true);

the result would consist of 0 item because it is a case-sensitive search.

result = All.FindByMemberAccess("MyClass", "dataMember", false);

the result would consist of 1 item:
    a.DataMember (in a.DataMember = 3)

result = All.FindByMemberAccess("MyClass", "met*", true);
```

the result would consist of 0 item, because it is a case-sensitive search.

```
result = All.FindByMemberAccess("MyClass", "met*", false);
```

the result would consist of 1 item:

```
    a.Method (in b = a.DataMethod())
```

4.40 CxList.FindByExactMemberAccess Method (string)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. Notice that this is a case-sensitive search. For a non case-sensitive search, please use the FindByExactMemberAccess Method (string, bool) instead.

Syntax

```
CxQL  
public CxList FindByExactMemberAccess(string memberAccess)
```

Parameters

memberAccess

Contains both the name of the type and the name of the accessed member in the qualified notation (eg. "CheckBoxList.SelectedValue").

Return Value

A subset of "this" instance where its elements are the ones which their given member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.FindByMemberAccess() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
result = All.FindByExactMemberAccess("MyClass.DataMember");  
the result would consist of 1 item:  
    a.DataMember (in a.DataMember = 3)
```

Version Information

Supported from v8.2.0

4.41 CxList.FindByExactMemberAccess

Method (string,bool)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. This search allows both case-sensitive and non case-sensitive searches.

Syntax

```
CxQL
public CxList FindByMemberAccess(string memberAccess, bool caseSensitive)
```

Parameters

memberAccess

Contains both the name of the type and the name of the accessed member in qualified notation (eg. "CheckBoxList.SelectedValue").

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByMemberAccess() method.
The input source code is:

MyClass a;
int b;
a.DataMember = 3;
b = a.Method();
result = All.FindByExactMemberAccess("MyClass.dataMember", true);
Notice that the result would consist of 0 items because the search is case-sensitive.

result = All.FindByExactMemberAccess("MyClass.dataMember", false);
The result would consist of 1 item:
    a.DataMember (in a.DataMember = 3)
```

Version Information

Supported from v8.2.0

4.42 CxList.FindByExactMemberAccess

Method (string,string)

Returns a CxList which is a subset of "this" instance where its elements are the ones that match the given member being accessed. This is a case-sensitive search by both the name of the type and the name of the accessed member. For a non case-sensitive search please use the `FindByExactMemberAccess Method(string, string, bool)` instead.

Syntax

```
CxQL
public CxList FindByExactMemberAccess(string typeName, string memberName)
```

Parameters

typeName

Contains the name of the accessed type (eg. "CheckBoxList");

memberName

Contains the name of the accessed member (eg. "SelectedValue");

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByMemberAccess() method.
The input source code is:
MyClass a;
int b;
a.DataMember = 3;
b = a.Method();
result = All.FindByExactMemberAccess("MyClass", "DataMember");

The result would consist of 1 item:
    a.DataMember (in a.DataMember = 3)
```

Version Information

Supported from v8.2.0

4.43 CxList.FindByExactMemberAccess

Method (string, string, bool)

Returns a CxList which is a subset of this instance where its elements are the ones that match the given member being accessed. This search allows both case-sensitive and non case-sensitive searches by the type name and the name of the accessed member.

Syntax

```
CxQL
public CxList FindByExactMemberAccess(string typeName, string memberName,
bool caseSensitive)
```

Parameters

typeName

Contains the name of the accessed type (eg. "CheckBoxList");

memberName

Contains the name of the accessed member (eg. "SelectedValue");

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance where its elements are the ones which their specified member is accessed.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByMemberAccess() method.
The input source code is:
MyClass a;
int b;
a.DataMember = 3;
b = a.Method();
result = All.FindByExactMemberAccess("MyClass", "dataMember", true);
the result would consist of 0 item because it is a case-sensitive search.
result = All.FindByExactMemberAccess("MyClass", "dataMember", false);

the result would consist of 1 item:
a.DataMember (in a.DataMember = 3)
```

Version Information

Supported from v8.2.0

4.44 CxList.FindByMethodReturnType Method (string)

Returns a CxList which is a subset of "this" instance and its elements are method declarators of a given return type.

Syntax

```
CxQL  
public CxList FindByMethodReturnType(string type)
```

Parameters

type

The return type name string.

Return Value

A subset of "this" instance with method declarators of a given return type.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByMethodReturnType() method.  
The input source code is:  
  
MyType foo() {  
    ...  
}  
  
result = All.FindByMethodReturnType("MyType");  
  
the result would consists of 1 item:  
    foo
```

4.45 CxList.FindByName Method (string)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their name is the given parameter.

Syntax

```
CxQL  
public CxList FindByName(string name)
```

Parameters

name

The name of the objects to look for. Prefix and postfix wildcard (*) are supported.

Return Value

A subset of "this" instance and its elements are the ones which their name is the given parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByName("*Member*");  
  
the result would consist of 1 item:  
    a.DataMember (in a.DataMember = 3)
```

4.46 CxList.FindByName Method (string, int, int)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their name is the given parameter (optionally with wildcards) and is not shorter than minLength and not longer than maxLength.

Syntax

```
CxQL  
public CxList FindByName(string name, int minLength, int maxLength)
```

Parameters

name

Contains the name of the objects. Prefix and postfix wildcard (*) are supported.

minLength

Minimum length of the searched strings.

maxLength

Maximum length of the searched strings.

Result

A subset of "this" instance and its elements are the ones which their name is the given parameter, according to the given length interval.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByName("*Me*", 3, 7);  
the result would consist of 1 item:  
Method (in b = a.Method())
```

Version Information

Supported from v2.0.5

4.47 CxList.FindByName Method (string, bool)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their name is the given parameter, according to the specified comparison criteria.

Syntax

```
CxQL  
public CxList FindByName(string name, bool caseSensitive)
```

Parameters

name

Contains the name of the objects. Prefix and postfix wildcard (*) are supported.

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance and its elements are the ones which their name is the given parameter, according to the given comparison criteria. The caseSensitive boolean value defines the ability to search using case sensitive or case insensitive comparison.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CXQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByName("*member*", true);  
the result would consist of 0 items.  
  
result = All.FindByName("*member*", false);  
the result would consist of 1 item:  
a.DataMember (in a.DataMember = 3)
```

Version Information

Supported from v1.8.1

4.48 CxList.FindByName Method (string, StringComparison)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their name is the given parameter. The comparison method specified in parameter is used for matching.

Syntax

```
CxQL  
public CxList FindByName(string name, StringComparison comparisonType)
```

Parameters

name

The name of the objects to look for. Prefix and postfix wildcard (*) are supported.

comparisonType

StringComparison type to be used in name comparison. One of the following values:

CurrentCulture, CurrentCultureIgnoreCase, InvariantCulture, InvariantCultureIgnoreCase, Ordinal, OrdinalIgnoreCase

Return Value

A subset of "this" instance and its elements are the ones which their name is the given parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByName("*member*", StringComparison.OrdinalIgnoreCase);  
the result would consist of 1 item:  
    DataMember (in a.DataMember = 3)
```

4.49 CxList.FindByName Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their names are equal to the given list.

Syntax

```
CxQL  
public CxList FindByName(CxList nodesList)
```

Parameters

nodesList

The list of nodes containing the names to be found.

Return Value

A subset of "this" instance and its elements are the ones which the name is contained in the given list.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByName(All.FindByType(typeof(MemberAccess)));  
  
the result would consist of 3 items:  
a (in MyClass a)  
a (in a.DataMember = 3)  
a (in b = a.Method())
```

4.50 CxList.FindByName Method

(CxList, bool)

Returns a CxList which is a subset of "this" instance and its elements are the ones which their names are equal to the list given.

Syntax

```
CxQL  
public CxList FindByName(CxList nodesList, bool CaseSensitive)
```

Parameters

nodesList

The list of nodes containing the names to be found.

CaseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of "this" instance and its elements are the ones which their name is contained in the given list, according to the specified case sensitivity comparison criteria.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByName() method.  
The input source code is:  
  
MyClass A;  
int a;  
A.DataMember = 3;  
a = A.Method();  
  
result = All.FindByName(All.FindByType(typeof(MemberAccess)), false);  
  
the result would consist of 5 items:  
  A (in MyClass A)  
  a (in int a)  
  A (in A.DataMember = 3)  
  a (in a = A.Method())  
  A (in a = A.Method())
```

4.51 CxList.FindByParameterName(string)

Returns a CxList which is a subset of "this", containing only MethodInvokeExpr DOM node where their arguments are labeled according to the given value.

Syntax

```
CxQL  
public CxList FindByParameterName (string paramName)
```

Parameters

paramName

String containing the name of the parameter belonging to the resultant methods.

Return Value

A subset of "this" instance where its elements are MethodInvokeExpr and contain arguments labelled according to 'paramName'.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByParameterName(string) method.  
The input source code is:  
  
class NamedExample  
{  
    static void Main(string[] args)  
    {  
        PrintOrderDetails(sellerName:"Gift Shop",31,productName:"Red Mug");  
    }  
}  
  
result = All.FindByParameterName ("sellerName");  
  
the result would consist in 1 item:  
    PrintOrderDetails
```

4.52 CxList.FindByParameterName(string, int)

Returns a CxList which is a subset of "this", containing only MethodInvokeExpr DOM node where their arguments on a given position are labeled according to the given value.

Syntax

```
CxQL
public CxList FindByParameterName (string paramName, int paramPosition)
```

Parameters

paramName

String containing the name of the parameter belonging to the resultant methods.

paramPosition

Zero based index indicating the position of argument named 'paramName'.

Return Value

A subset of "this" instance where its elements are MethodInvokeExpr and contain arguments labelled according to 'paramName' in the indicated position by 'paramPosition'.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByParameterName(string, int)
method.
The input source code is:

class NamedExample
{
    static void Main(string[] args)
    {
        PrintOrderDetails(sellerName:"Gift Shop",31,productName:"Red Mug");
    }
}

result = All.FindByParameterName ("sellerName", 1);

would have no results because there's no argument named "sellerName" on the
first position of the method call.
However,
result = All.FindByParameterName ("productName", 1);

would result in 1 item:
    PrintOrderDetails
```

Because there's an argument on the second position(zero based) called
"productName"

4.53 CxList.FindByParameters Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are methods of the given CxList with the specified parameters.

Syntax

```
CxQL  
public CxList FindByParameters (CxList paramList)
```

Parameters

paramList

CxList of method parameters.

GetArrayOfNodeIds

Return Value

A subset of "this" instance with methods whose parameters are given in the list.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByParameters() method.  
The input source code is:  
  
foo("myVar");  
  
CxList var = All.FindByShortName("myVar");  
result = All. FindByParameters(var);  
  
the result would consist of 1 item:  
foo
```

4.54 CxList.FindByParameterValue

Method (int, string, BinaryOperator)

Returns a CxList which is a subset of "this" instance with methods where a given parameter number is equal (or not) to the specified value.

Syntax

```
CxQL
public CxList FindByParameterValue(int ParamNo, string ParamValue,
    BinaryOperator opr)
```

Parameters

ParamNo

Zero-based index of the parameter

ParamValue

The value of the parameter

BinaryOperator

One of the followings values:

```
BinaryOperator.IdentityEquality
BinaryOperator.IdentityInequality
```

Return Value

Returns a CxList which is a subset of "this" instance with methods where a given parameter number is equal (or not) to the specified value.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
This example demonstrates the CxList.FindByParameterValue() method.
The input source code is:
a = Method("val1", 1);
a = Method("val2", 2);
result = All.FindByParameterValue(0,"val1",BinaryOperator.IdentityEquality);
    the result would consist of 1 item:
        Method (in a = Method("val1", 1))
result=All.FindByParameterValue(0,"val1",BinaryOperator.IdentityInequality);
    the result would consist of 1 item:
        Method (in a = Method("val2", 2))
result=All.FindByParameterValue(1,"2",BinaryOperator.IdentityEquality);
    the result would consist of 1 item:
        Method (in a = Method("val2", 2))
```

4.55 CxList.FindByParameterValue

Method (int, int, BinaryOperator)

Returns a CxList which is a subset of "this" instance and its elements are methods whose parameters values (referred by their index) are equal (or not).

Syntax

```
CxQL  
public CxList FindByParameterValue(int paramNo1, int paramNo2,  
BinaryOperator opr)
```

Parameters

paramNo1

Zero-based index of the parameter.

paramNo2

Zero-based index of the parameter.

opr

One of the following values:

`BinaryOperator.IdentityEquality`

`BinaryOperator.IdentityInequality`

Return Value

A subset of "this" instance whose parameter values are equal or not equal (depending on the operator chosen).

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.GetParameters() method.  
The input source code is:  
  
foo(1, i, 1);  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
result = All.FindByParameterValue(0, 2, BinaryOperator.IdentityEquality);  
  
the result would consist of 1 item:  
    foo (first parameter value is equal to the third one)
```

4.56 CxList.FindByPointerType Method (string, int, bool)

Returns a CxList which is a subset of "this" instance and its elements are of the type pointer of the specified type of code element

Syntax

```
CxQL  
public CxList FindByPointerType(string type, int maxDepth, bool  
caseSensitive)
```

Parameters

type

type of the parameter

maxDepth

Zero-based maximum depth to look for. Default value is 0 meaning that it will look all the PointerTypeRef levels until it finds a TypeRef

caseSensitive

Default value is true

Return Value

A subset of "this" instance and its elements are of the type pointer of the specified type of code element.

Exceptions

Exception type	Condition
ArgumentNullException	type is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPointerType method.  
The input source code is:  
  
var i *int  
  
result = All.FindByPointerType("int");  
  
the result would consist of 2 items:  
    *int - pointer  
    i - Declarator
```

Version Information

Supported from v8.5.0

4.57 CxList.FindByPointerType Method (string, bool)

Returns a CxList which is a subset of “this” instance and its elements are of the type pointer of the specified type of code element

Syntax

```
CxQL  
public CxList FindByPointerType(string type, bool caseSensitive)
```

Parameters

type

type of the parameter

caseSensitive

Default value is true

Return Value

A subset of “this” instance and its elements are of the type pointer of the specified type of code element.

Exceptions

Exception type	Condition
ArgumentNullException	type is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPointerType method.  
The input source code is:  
  
var i *int  
  
result = All.FindByPointerType("int");  
  
the result would consist of 2 items:  
    *int - pointer  
    I - Declarator
```

Version Information

Supported from v8.5.0

4.58 CxList.FindByPointerType Method (string[], int, bool)

Returns a CxList which is a subset of "this" instance and its elements are of the type pointer of the specified types of code element

Syntax

```
CxQL  
public CxList FindByPointerType(string[] type, int maxDepth, bool  
caseSensitive)
```

Parameters

type

types of the parameter

maxDepth

Zero-based maximum depth to look for. Default value is 0 meaning that it will look all the

PointerTypeRef levels until it finds a TypeRef

caseSensitive

Default value is true

Return Value

A subset of "this" instance and its elements are of the type pointer of the specified types of code element.

Exceptions

Exception type	Condition
ArgumentNullException	type is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPointerType method.  
The input source code is:  
  
var i *int  
  
result = All.FindByPointerTypes(new string[]{"int","string"});  
  
the result would consist of 2 items:  
    *int - pointer  
    i - Declarator
```

Version Information

Supported from v8.5.0

4.59 CxList.FindByPointerType Method (string[], bool)

Returns a CxList which is a subset of "this" instance and its elements are of the type pointer of the specified types of code element

Syntax

```
CxQL  
public CxList FindByPointerType(string[] type, bool caseSensitive)
```

Parameters

type

types of the parameter

caseSensitive

Default value is true

Return Value

A subset of "this" instance and its elements are of the type pointer of the specified types of code element.

Exceptions

Exception type	Condition
ArgumentNullException	type is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPointerType method.  
The input source code is:  
  
var i *int  
  
result = All.FindByPointerTypes(new string[]{"int","string"});  
  
the result would consist of 2 items:  
    *int - pointer  
    i - Declarator
```

Version Information

Supported from v8.5.0

4.60 CxList.FindByPosition Method (int)

Returns a CxList which is a subset of "this" instance and its elements are in the given line number.

Syntax

```
CxQL  
public CxList FindByPosition(int line)
```

Parameters

line

The line number.

Return Value

A subset of "this" instance with elements from the given line.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPosition() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = 6;  
  
result = All.FindByPosition(2);  
  
the result would consist of 4 items:  
    if  
    a,  
    >,  
    3
```

4.61 CxList.FindByPosition Method (int, int)

Returns a CxList which is a subset of "this" instance and its elements are located in the given line and column number.

Syntax

```
CxQL  
public CxList FindByPosition(int line, int col)
```

Parameters

Line

Line number in the source code.

Col

Column number in the source code.

Return Value

A subset of "this" instance with elements from the given line and column.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPosition() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByPosition (3, 16);  
the result would consist of 1 item:  
3 (in a.DataMember = 3)
```

4.62 CxList.FindByPosition Method (int, int, int)

Returns a CxList which is a subset of "this" instance and its elements are in the given line/column and with the given length.

Syntax

```
CxQL  
public CxList FindByPosition(int line, int col, int length)
```

Parameters

line

The line number.

col

The column number.

length

The element length.

Return Value

A subset of "this" instance with elements from the given line, column and with the given length.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPosition() method.  
The input source code is:  
  
int b, a = 5;  
if (a == 33)  
    b = 6;  
  
result = All.FindByPosition(2, 5, 1);  
  
the result would consist of 1 item:  
    a
```

4.63 CxList.FindByPosition Method (string, int)

Returns a CxList which is a subset of “this” instance and its elements are located in the given file and line number.

Syntax

```
CxQL  
public CxList FindByPosition(string file, int line)
```

Parameters

file

File name in the source code.

line

Line number in the source code.

Return Value

A subset of “this” instance which is located in the given file and line.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPosition() method.  
The input source code is (file name "Mycode.java"):  
  
MyClass a;  
int b;  
a.DataMember = 5;  
b = a.Method();  
  
result = All.FindByPosition ("MyCode.java", 3);  
the result would consist of 1 item:  
5 (in a.DataMember = 5)
```

4.64 CxList.FindByPosition Method

(string, int, int)

Returns a CxList which is a subset of "this" instance and its elements are located in the given file, line and column.

Syntax

```
CxQL  
public CxList FindByPosition(string file, int line, int col)
```

Parameters

file

File name in the source code.

line

Line number in the source code.

col

Column number in the source code.

Return Value

A subset of "this" instance which is located in the given file, line and column.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

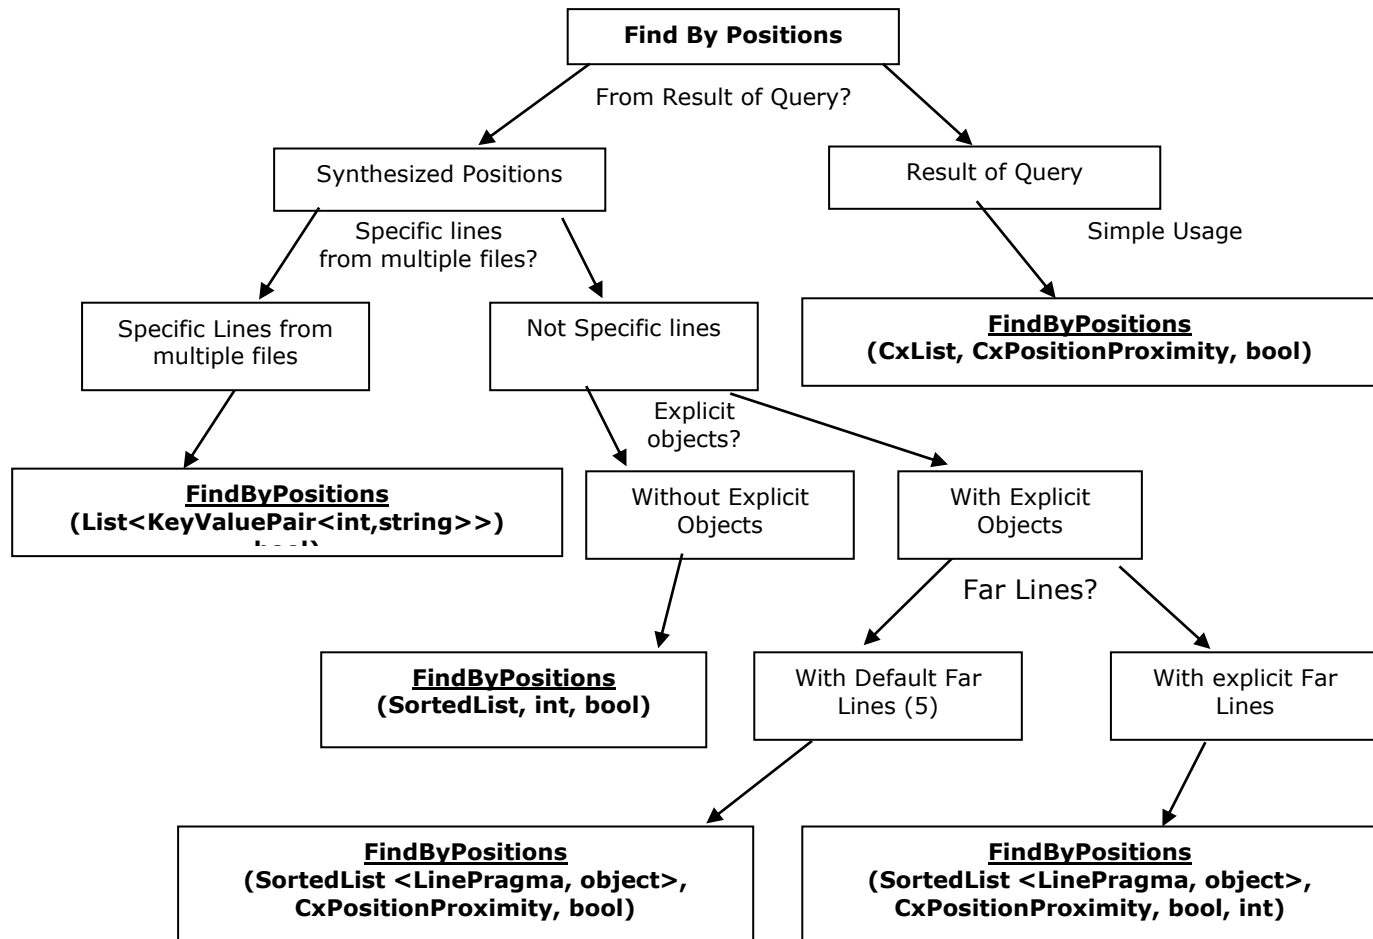

Example

```
CxQL  
  
This example demonstrates the CxList.FindByPosition() method.  
file name "Mycode.java"  
The input source code is:  
MyClass a;  
int b;  
a.DataMember = 5;  
b = a.Method();  
  
result = All.FindByPosition ("MyCode.java", 3, 16);  
the result would be -  
1 item found:  
5 (in a.DataMember = 5)
```

4.65 CxList.FindByPositions Methods

There are four methods (atomic queries) for using the "Find By Positions" method CxQL.

The recommended selection between the possible methods should be done according to the following tree:

4.65.1 CxList.FindByPositions Method (SortedList, int, bool)

Finds the elements of "this" instance at positions given in the pragmas list.

Syntax

```
CxQL
public CxList FindByPositions(SortedList pragmas, int extendMatch, bool
oneOnly)
```

Parameters

pragmas

A sorted list containing the pragmas to match.

extendMatch

Defines the closeness of the matching results:

0 => ExactMatch: find exact match

1 => FindInLine: extend search to objects in closest position within same line

2 => FindClosestMatch: extend match to closest position within the same file

oneOnly

If true, it returns one result per position.

Return Value

The elements from "this" instance that are at the required positions.

Exceptions

Exception type	Condition
ArgumentNullException	First parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

CxQL
 This example demonstrates the `CxList.FindByPositions()` method.
 The input source code is:

```
int b, a = 5;
if (a == 33)
    b = 6;
```

```
CxList list = All.FindByShortName("b");
SortedList sorted = new SortedList(new PragmaComparer());
foreach (KeyValuePair<int, IGraph> dic in list.data)
{
    sorted.Add(dic.Value.LinePragma, null);
}
result = All.FindByPositions(sorted, 1, true);
```

the result would consist of 2 items:
 b (in int b)
 b (in b = 6)

4.65.2 CxList.FindByPositions Method (CxList, CxPositionProximity, bool)

Finds the elements of "this" instance at positions given in the list using the proximity given in parameter.

Syntax

```
CxQL
public CxList FindByPositions(CxList positions, CxPositionProximity
extendMatch, bool oneOnly)
```

Parameters

positions

A list containing the pragmas to match.

extendMatch

Defines the closeness of the matching results. One of the following values:

ExactMatch: find exact match

FindInLine: extend search to objects in closest position within same line

FindClosestMatch: extend match to closest position within the same file

oneOnly

If true, it returns one result per position.

Return Value

The elements of “this” instance that are at the given positions.

Exceptions

Exception type	Condition
ArgumentNullException	First parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

CxQL

```
This example demonstrates the CxList.FindByPositions() method.
The input source code is:
```

```
int b, a = 5;
if (a == 33)
    b = 6;
```

```
CxList list = All.FindByName("b");
result = All.FindByPositions(list, CxPositionProximity.FindInLine, false);
```

```
the result would be all the elements in the 5 lines closer to lines that
appear variable b -
```

```
2 items found
    b (in int b)
    b (in b = 6)
```

4.65.3 CxList.FindByPositions Method (SortedList<LinePragma,object>, CxPositionProximity, bool)

Finds the elements of “this” instance at positions given in the pragmas list using the proximity from the parameter.

Syntax

CxQL

```
public CxList FindByPositions(SortedList<LinePragma,object> pragmas,
CxPositionProximity extendMatch, bool oneOnly)
```

Parameters
pragmas

A sorted list containing the pragmas to match.

extendMatch

Defines the closeness of the matching results. One of the following values:

FindInLine: extend search to objects in closest position within same line.

FindClosestMatch: extend match to closest position within the same file.

ExactMatch: find exact match.

oneOnly

If true, it returns one result per position.

Return Value

The elements from the current instance that are at the given positions.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL

This example demonstrates the CxList.FindByPositions() method.
The input source code is:

int b, a = 5;
if (a == 33)
    b = 6;

CxList list = All.FindByName("b");
SortedList<LinePragma, object> sorted =
new SortedList<LinePragma, object>(new DataCollections.PragmaComparer());

foreach (KeyValuePair<int, IGraph> dic in list.data) {
    sorted.Add(dic.Value.LinePragma, null);
}

result = All.FindByPositions(sorted, CxList.CxPositionProximity.FindInLine,
true);

the result would consist of 2 items:
    b (in int b)
    b (in b = 6)
```

4.65.4 CxList.FindByPositions Method (SortedList<LinePragma,object>, CxPositionProximity, bool, int)

Finds the elements of "this" instance at positions given in the pragmas list using the proximity given in parameter.

Syntax

```
CxQL
public CxList FindByPositions(SortedList<LinePragma,object> pragmas,
CxPositionProximity extendMatch, bool oneOnly, int farLines)
```

Parameters

pragmas

A sorted list containing the pragmas to match.

extendMatch

Defines the closeness of the matching results. One of the following values:

FindInLine: extend search to objects in closest position within same line.

FindClosestMatch: extend match to closest position within the same file.

ExactMatch: find exact match.

oneOnly

If true, it returns one result per position.

farLines

Acceptable line distance to look for (the default recommended setting is 5).

Return Value

The elements from “this” instance that are at the given positions.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

This example demonstrates the `CxList.FindByPositions()` method.
 The input source code is:

```
int b, a = 5;
if (a == 33)
    b = 6;
```

```
CxList list = All.FindByName("b");
SortedList<LinePragma, object> sorted =
new SortedList<LinePragma, object>(new DataCollections.PragmaComparer());
```

```
foreach (KeyValuePair<int, IGraph> dic in list.data) {
    sorted.Add(dic.Value.LinePragma, null);
}
```

```
result = All.FindByPositions(sorted, CxList.CxPositionProximity.FindInLine,
true, 5);
```

```
the result would consist of 2 items:
    b (in int b)
    b (in b = 6)
```

4.65.5 CxList.FindByPositions Method (List<KeyValuePair<int, string>>)

Finds the elements of “this” instance at lines of files given in parameter.

Syntax

```
CxQL
public CxList FindByPositions(List<KeyValuePair<int, string>> lines)
```

Parameters

lines

A list of pairs line/filename to search the elements.

Return Value

The subset of elements from “this” instance that are in the files given at the lines requested.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

CxQL

This example demonstrates the `CxList.FindByPositions()` method.
The input source code is (file name is “MyCode.cs”):

```
int b, a = 5;
if (a == 33)
    b = 6;
```

```
KeyValuePair<int,string> position= new
KeyValuePair<int,string>(3,"path\\MyCode.cs");
List<KeyValuePair<int,string>> list = new List<KeyValuePair<int,string>>();
list.Add(position);
result = All.FindByPositions(list);
```

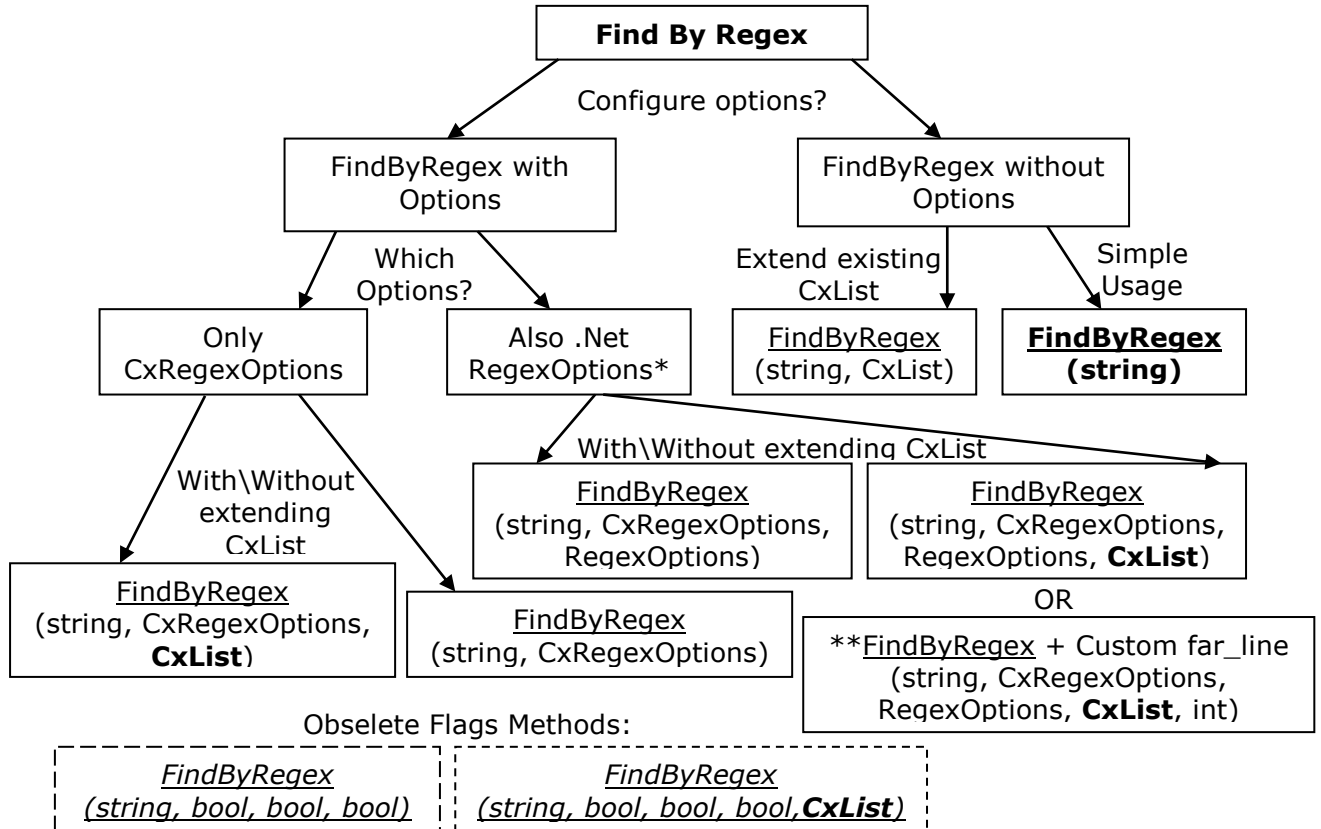

the result would consist of 3 items:

```
    b
    =
    6
```

4.66 CxList.FindByRegex Methods

There are few methods (atomic queries) for using the "Find By Regex" algorithm in CxQL, some of them are obsolete and not recommended, and some of them are more comfortable according to the required parameters scenario.

The recommended selection between the possible methods should be done according to the following tree:

- Even without mentioning it explicitly in the parameter, the `RegexOptions.Multiline` and `RegexOptions.Singleline` are always enabled in the Find-By-Regex algorithm in these queries.
- Customizing the FAR_LINES parameter is possible using the new method (the default value of this parameter is 5 and it is relevant for searching regex matches in comments).
- The full path (including namespaces) of the `CxRegexOptions` enum is `CxList.CxRegexOptions`.
- The full path (including namespaces) of the `RegexOptions` enum is `System.Text.RegularExpressions.RegexOptions`.

4.66.1 CxList.FindByRegex Method (string)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- `FindByRegex(expression, null)`
- `FindByRegex(expression, CxRegexOptions.None)`
- `FindByRegex(expression, CxRegexOptions.None, RegexOptions.None)`
- `FindByRegex(expression, CxRegexOptions.None, RegexOptions.None, null)`
- `FindByRegex(expression, CxRegexOptions.None, RegexOptions.None, null, 5)`

- FindByRegex(expression, `false`, `true`, `false`)
- FindByRegex(expression, `false`, `true`, `false`, `null`)
- FindByRegex(expression, `CxRegexOptions.None`, `null`)

Syntax

```
CxQL
public CxList FindByRegex(string expression)
```

Parameters

expression

Regular expression string.

Return Value

A subset of this instance matches the given regular expression.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

```
CxQL

This example demonstrates the CxList.FindByRegex() method.
The input source code is:

int a = 5;
if (a > 3)
    foo(a);

result = All.FindByRegex(@"(\s)?foo\(");

the result would be -
  1 item found:
  foo
```

Version Information

Supported from: **CxAudit** v1.8.1

4.66.2 CxList.FindByRegex Method (string, bool, bool, bool)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified flag parameters.

This call is equivalent to the following calls and it is highly recommended to use the enum instead of the confusing flags:

- FindByRegex(expression, searchInComments, searchInStringLiterals, recursive, `null`)

- The 3 flags are translated to `CxRegexOptions` enum in the following way (bitmask supported):
 - `(false, false, false) =>`
`CxRegexOptions.DoNotSearchInStringLiterals`
 - `(false, false, true) =>`
`CxRegexOptions.DoNotSearchInStringLiterals |`
`CxRegexOptions.AllowOverlaps`
 - `(false, true, false) =>` `CxRegexOptions.None`
 - `(false, true, true) =>` `CxRegexOptions.AllowOverlaps`
 - `(true, false, false) =>`
`CxRegexOptions.SearchInComments |`
`CxRegexOptions.DoNotSearchInStringLiterals`
 - `(true, false, true) =>`
`CxRegexOptions.SearchInComments |`
`CxRegexOptions.DoNotSearchInStringLiterals |`
`CxRegexOptions.AllowOverlaps`
 - `(true, true, false) =>` `CxRegexOptions.SearchInComments`
 - `(true, true, true) =>`
`CxRegexOptions.SearchInComments |`
`CxRegexOptions.AllowOverlaps`

After translating the flags to `CxRegexOptions` enum this call is equivalent to the following calls:

- `FindByRegex(expression, cxRegexOptions)`
- `FindByRegex(expression, cxRegexOptions, RegexOptions.None)`
- `FindByRegex(expression, cxRegexOptions, RegexOptions.None, null)`
- `FindByRegex(expression, cxRegexOptions, RegexOptions.None, null, 5)`
- `FindByRegex(expression, cxRegexOptions, null)`

Syntax

```
CxQL
public CxList FindByRegex(string expression , bool searchInComments, bool
searchInStringLiterals, bool recursive)
```

Parameters

expression

Regular expression string.

searchInComments

Positive if searching inside comments is desired.

searchInStringLiterals

Positive if searching inside string literals is desired.

recursive

Positive if it is desired to allow regex matches to overlap.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CxQL

```
This example demonstrates the CxList.FindByRegex() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", false, true, false);
```

```
the result would be -
  1 item found:
    foo
```

Version Information

Supported from v1.8.1

4.66.3 CxList.FindByRegex Method (string, bool, bool, bool, CxList)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified flag parameters and fill the extended results parameter with the strings of the matches.

- The 3 flags are translated to [CxRegexOptions](#) enum in the following way (bitmask supported):
 - (false, false, false) => [CxRegexOptions.DoNotSearchInStringLiterals](#)
 - (false, false, true) =>

```
CxRegexOptions.DoNotSearchInStringLiterals |
CxRegexOptions.AllowOverlaps
```
 - (false, true, false) => [CxRegexOptions.None](#)
 - (false, true, true) => [CxRegexOptions.AllowOverlaps](#)
 - (true, false, false) =>

```
CxRegexOptions.SearchInComments |
CxRegexOptions.DoNotSearchInStringLiterals
```
 - (true, false, true) =>

```
CxRegexOptions.SearchInComments |
CxRegexOptions.DoNotSearchInStringLiterals |
CxRegexOptions.AllowOverlaps
```
 - (true, true, false) => [CxRegexOptions.SearchInComments](#)

- (true, true, true) =>

[CxRegexOptions.SearchInComments](#) | [CxRegexOptions.AllowOverlaps](#)

After translating the flags to [CxRegexOptions](#) enum this call is equivalent to the following calls:

(It is highly recommended to use the enum instead of the confusing flags)

- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), cxList)
- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), cxList, 5)
- FindByRegex(expression, cxRegexOptions, cxList)

Syntax

CxQL

```
public CxList FindByRegex(string expression , bool searchInComments, bool
searchInStringLiterals, bool recursive, CxList extendedResults)
```

Parameters

expression

Regular expression string.

searchInComments

Positive if searching inside comments is desired.

searchInStringLiterals

Positive if searching inside string literals is desired.

recursive

Positive if it is desired to allow regex matches to overlap.

extendedResults

extendedResults parameter is filled with the strings of the matches.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CxQL

```
This example demonstrates the CxList.FindByRegex() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", false, true, false, All.NewCxList());
```

```
the result would be -
1 item found:
```

`foo`

Version Information

Supported from v1.8.1

4.66.4 CxList.FindByRegex Method (string, CxList)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, and fill the extended results parameter with the strings of the matches.

This query search source files with regex, and return the closest same line DOM object to the matches.

If no such object exists, returns the closest object in a successive line.

Search does not include searching inside comments and string literals, and regex matches are not allowed to overlap. The matching strings are returned in the extendedResults paramater.

This call is equivalent to the following calls:

- FindByRegex(expression, CxRegexOptions.None, RegexOptions.None, cxList)
- FindByRegex(expression, CxRegexOptions.None, RegexOptions.None, cxList, 5)
- FindByRegex(expression, false, true, false, cxList)
 - Using the Boolean flags option is not recommended, use the enums instead.
- FindByRegex(expression, CxRegexOptions.None, cxList)

Syntax

```
CxQL  
public CxList FindByRegex(string expression , CxList extendedResults)
```

Parameters

expression

Regular expression string.

extendedResults

extendedResults parameter is filled with the strings of the matches.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

```
CXQL
```

```
This example demonstrates the CxList.FindByRegex() method.  
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);

result = All.FindByRegex(@"(\s)?foo\(", All.NewCxList());

the result would be -
1 item found:
foo
```

Version Information

Supported from v1.8.1

4.66.5 CxList.FindByRegex Method (string, CxRegexOptions)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified Checkmarx Regex Options defined in the second parameter.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#))
- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), null)
- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), null, 5)
- FindByRegex(expression, cxRegexOptions, null)

Syntax

```
CxQL
public CxList FindByRegex(string expression , CxRegexOptions cxOptions)
```

Parameters

expression

Regular expression string.

cxOptions

An enum matching the relevant CxRegexOptions which are:

[None](#), [SearchInComments](#), [DoNotSearchInStringLiterals](#), [AllowOverlaps](#) and

[SearchOnlyInComments](#)

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CxQL

```
This example demonstrates the CxList.FindByRegex() method.  
The input source code is:
```

```
int a = 5;  
if (a > 3)  
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", CxList.CxRegexOptions.None);
```

```
the result would be -  
1 item found:  
    foo
```

Version Information

Supported from v1.8.1

4.66.6 CxList.FindByRegex Method (string, CxRegexOptions, CxList)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified Checkmarx Regex Options defined in the second parameter, and also fill the extended results parameter with the strings of the matches.

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), cxList)
- FindByRegex(expression, cxRegexOptions, [RegexOptions.None](#), cxList, 5)

Syntax

CxQL

```
public CxList FindByRegex(string expression , CxRegexOptions cxOptions,  
CxList extendedResults)
```

Parameters

expression

Regular expression string.

cxOptions

An enum matching the relevant CxRegexOptions which are:

[None](#), [SearchInComments](#), [DoNotSearchInStringLiterals](#), [AllowOverlaps](#) and

[SearchOnlyInComments](#)

extendedResults

extendedResults parameter is filled with the strings of the matches.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CxQL

```
This example demonstrates the CxList.FindByRegex() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", CxList.CxRegexOptions.None,
All.NewCxList());
```

```
the result would be -
1 item found:
foo
```

Version Information

Supported from v1.8.1

4.66.7 CxList.FindByRegex Method (string, CxRegexOptions, RegexOptions)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified Regex Options defined in the parameters ([Checkmarx regex options](#) and [standard regex options](#)).

This call is equivalent to the following calls and it is recommended to use the short call format by default:

- FindByRegex(expression, cxRegexOptions, regexOptions, null)
- FindByRegex(expression, cxRegexOptions, regexOptions, null, 5)

Syntax

CxQL

```
public CxList FindByRegex(string expression , CxRegexOptions cxOptions,
RegexOptions regularOptions)
```

Parameters

expression

Regular expression string.

cxOptions

An enum matching the relevant CxRegexOptions which are:

[None](#), [SearchInComments](#), [DoNotSearchInStringLiterals](#), [AllowOverlaps](#) and

[SearchOnlyInComments](#)

regularOptions

Options to add to the regular expression (case sensitivity, etc.)

In addition to the user-defined regular-expression-options in this arguments, the algorithm also uses the following regex-options by default: [RegexOptions.Multiline](#), [RegexOptions.Singleline](#).

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CxQL

```
This example demonstrates the CxList.FindByRegex() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", CxList.CxRegexOptions.None,
System.Text.RegularExpressions.RegexOptions.None);
```

```
the result would be -
1 item found:
foo
```

Version Information

Supported from v1.8.1

4.66.8 CxList.FindByRegex Method (string, CxRegexOptions, RegexOptions, CxList)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified Regex Options defined in the parameters ([Checkmarx regex options](#) and [standard regex options](#)), and also fill the extended results parameter with the strings of the matches.

This call is equivalent to the following call and it is recommended to use the short call format by default:

- FindByRegex(expression, cxRegexOptions, regexOptions, cxList, 5)

Syntax

CxQL

```
public CxList FindByRegex(string expression, CxRegexOptions cxOptions,
RegexOptions regularOptions, CxList extendedResults)
```

Parameters

expression

Regular expression string.

cxOptions

An enum matching the relevant CxRegexOptions which are:

None, SearchInComments, DoNotSearchInStringLiterals, AllowOverlaps and

SearchOnlyInComments

regularOptions

Options to add to the regular expression (case sensitivity, etc.)

In addition to the user-defined regular-expression-options in this arguments, the algorithm also uses the following regex-options by default: [RegexOptions.Multiline](#), [RegexOptions.Singleline](#).

extendedResults

extendedResults parameter is filled with the strings of the matches.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

CXQL

```
This example demonstrates the CxList.FindByRegex() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
```

```
result = All.FindByRegex(@"(\s)?foo\(", CxList.CxRegexOptions.None,
System.Text.RegularExpressions.RegexOptions.None, All.NewCxList());
```

```
the result would be -
1 item found:
foo
```

Version Information

Supported from v1.8.1

4.66.9 CxList.FindByRegex Method (string, CxRegexOptions, RegexOptions, CxList, int, CxPositionSearchDirection)

Returns a CxList which is a subset of this instance and its elements match the specified regular expression string, according to specified Regex Options defined in the parameters ([Checkmarx regex options](#) and [standard regex options](#)), and also fill the extended results parameter with the strings of the matches.

Also get a customized far-lines parameter to be considered as acceptable lines distance when looking for regex in comments.

All the other calls to "FindByRegex.." with \ without different parameters lead in the end to this specific method.

Syntax

CxQL

```
public CxList FindByRegex(string expression , CxRegexOptions cxOptions,
  RegexOptions regularOptions, CxList extendedResults, int farLines,
  CxPositionSearchDirection searchDirection )
```

Parameters

expression

Regular expression string.

cxOptions

An enum matching the relevant CxRegexOptions which are:

[None](#), [SearchInComments](#), [DoNotSearchInStringLiterals](#), [AllowOverlaps](#) and

[SearchOnlyInComments](#)

regularOptions

Options to add to the regular expression (case sensitivity, etc.)

In addition to the user-defined regular-expression-options in this arguments, the alogrith also uses the following regex-options by default: [RegexOptions.Multiline](#), [RegexOptions.Singleline](#).

extendedResults

extendedResults parameter is filled with the strings of the matches.

farLines

Configure the line distance to look for regex matches in comments (it is 5 lines by default).

searchDirection

Determines the search direction that can be one of the following values: Default, Backward, Forward. The Backward and Forward values means that the search is for the CxList which is a subset of the instance that is the last one before the regular expression or just the first one after, respectively. The default search (that is the default value of the parameter) just compares the distance between both (in manner of Line distance and column distance) and chooses the one that is the closest between the two.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegex method.

```
CXQL

This example demonstrates the CxList.FindByRegex() method.
The input source code is:

int a = 5;
if (a > 3)
    foo(a);

result = All.FindByRegex(@"(\s)?foo\(", CxList.CxRegexOptions.None,
System.Text.RegularExpressions.RegexOptions.None, All.NewCxList(), 5);

the result would be -
    1 item found:
        foo
```

Version Information

Supported from v1.8.1

4.66.10 CxList.FindByRegexSecondOrder Method (string, CxList)

Filters a CxList of Comments DOM objects according to a check of whether a Comment object contain a match to the provided regex expression, and returns closest DOM object to those that pass the filter.

Used in [C\C++ MISRA](#) Preset queries in order to validate comments style.

Syntax

```
CxQL
public CxList FindByRegexSecondOrder(string expression , CxList
extendedResults)
```

Parameters

expression

Regular expression search string.

inputList

The comments CxList that's should be filtered.

Return Value

A subset of this instance matches the given regular expression according to the additional parameters.

Exceptions

Exception type	Condition
ArgumentNullException	Expression parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the `FindByRegexSecondOrder` method
CxQL

```
This example demonstrates the CxList.FindByRegexSecondOrder() method.  
The input source code is taken from MISRA Code_Commented_Out query:  
  
/* Function comment is compliant. * /  
void mc2_0202 ( void )  
{  
use_int32(0); // Comment Not Compliant  
}  
*/  
  
// Find all comments ending with } or ;  
CxList extendedResult = All.NewCxList();  
  
// All /* */ comments  
CxList res = All.FindByRegex(@"\/\*.??\*/", true, false, false,  
extendedResult);  
  
// Search results for } or ; at end of comment  
result = All.FindByRegexSecondOrder(@"[;}]s*\*/", extendedResult);  
The result will be the commented out function which is found out by this  
regex
```

Version Information

Supported from v1.8.1

4.67 CxList.FindByRegexExt Methods

Find by regular expression in all files of the project regardless of DOM and language.

Remarks

The results are not related to DOM so they can't be compared to DOM objects returned by other functions. Results can't be used as parameters to other queries.

4.67.1 CxList.FindByRegexExt Method (string)

Syntax

```
CxQL  
public CxList FindByRegexExt(string pattern)
```

Parameters

Pattern

Regular expression pattern

Return Value

A list of matches for given regular expression in all project files.

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegexExt method.

```
CxQL  
  
This example demonstrates the CxList.FindByRegexExt() method.  
The input source code is:  
  
int a = 5;  
if (a > 3)  
    foo(a);  
else  
    FOO(a);  
  
// foo(a)  
/* foo */  
  
result = All.FindByRegexExt(@"(\s)?foo");  
  
the result would be -  
    3 items found:  
        foo  
        // FOO  
        /* foo
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.2 CxList.FindByRegexExt Method (string, string)

Syntax

```
CxQL
public CxList FindByRegexExt(string pattern, string fileMask)
```

Parameters

Pattern

Regular expression pattern

fileMask

File mask for search. Control characters "*" and "?" are supported.

Return Value

A list of matches for given regular expression in all project files.

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByRegexExt method.

```
CXQL

This example demonstrates the CxList.FindByRegexExt() method.
The input source code is:

int a = 5;
if (a > 3)
    foo(a);
else
    FOO(a);

// foo(a)
/* foo */

result = All.FindByRegexExt(@"(\s)?foo");

the result would be -
3 items found:
    foo
    // FOO
    /* foo
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.3 CxList.FindByRegexExt Method (string, string, bool)

Syntax

```
CxQL
public CxList FindByRegexExt(string pattern, string fileMask, bool
searchInComments)
```

Parameters

expression

Regular expression pattern

fileMask – optional

File mask for search. Control characters "*" and "?" are supported.

For example: "*.*)" looks in all files and "*.aspx" looks in aspx files.

searchInComments – optional

Allow or not search in comments

Return Value

A list of matches for given regular expression in chosen project files including or excluding results in comments.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

CxQL

```
This example demonstrates the CxList.FindByRegexExt() method.  
The input source code is:
```

```
int a = 5;  
if (a > 3)  
    foo(a);  
else  
    FOO(a);
```

```
// foo(a)  
/* foo */
```

```
result = All.FindByRegexExt(@"(\s)?foo", "*.cs", false,  
RegexOptions.IgnoreCase);
```

```
the result would be -  
1 item found:  
foo
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.4 CxList.FindByRegexExt Method (string, string, bool, RegexOptions)

Syntax

CxQL

```
public CxList FindByRegexExt(string pattern, string fileMask = "*.*)", bool  
searchInComments = true, RegexOptions regularOptions = RegexOptions.None)
```

Parameters

expression

Regular expression pattern

fileMask – optional

Default value: "*.*".

File mask for search. Control characters "*" and "?" are supported.

For example: "*.*" looks in all files and "*.aspx" looks in aspx files.

searchInComments – optional

Default value: true.

Allow or not search in comments

regularOptions – optional

Default value: RegexOptions.None.

Options for regular expression build from first parameter - **pattern**

Return Value

A list of matches for given regular expression in choosen project files including or excluding results in comments with regex build with specified options.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

CxQL

```
This example demonstrates the CxList.FindByRegexExt() method.  
The input source code is:
```

```
int a = 5;  
if (a > 3)  
    foo(a);  
else  
    FOO(a);
```

```
// foo(a)  
/* foo */
```

```
result = All.FindByRegexExt(@"(\s)?foo", "*.cs", false,  
RegexOptions.IgnoreCase);
```

```
the result would be -  
2 item found:  
    foo  
    FOO
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.5 CxList.FindByRegexExt Method (string, string, bool, CxRegexOptions ,RegexOptions)

Syntax

```
CxQL
public CxList FindByRegexExt(string pattern, string fileMask = " *.*", bool
searchInComments = true, CxRegexOptions cxOptions = CxRegexOptions.None,
RegexOptions regularOptions = RegexOptions.None)
```

Parameters

expression

Regular expression pattern

fileMask – optional

Default value: " *.*".

File mask for search. Control characters "*" and "?" are supported.

For example: " *.*" looks in all files and "*.aspx" looks in aspx files.

searchInComments – optional

Default value: true.

Allow or not search in comments

cxOptions

An enum matching the relevant CxRegexOptions which are:

None, SearchInComments, DoNotSearchInStringLiterals, AllowOverlaps and
SearchOnlyInComments

regularOptions – optional

Default value: RegexOptions.None.

Options for regular expression build from first parameter - **pattern**

Return Value

A list of matches for given regular expression in choosen project files including or excluding results in comments with regex build with specified options.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

```
CxQL
This example demonstrates the CxList.FindByRegexExt() method.
The input source code is:

int a = 5;
if (a > 3)
    foo(a);
else
    FOO(a);

// foo(a)
/* foo */
```

```
result = All.FindByRegexExt(@"(\s)?foo", "*.cs", false, CxRegexOptions.None,
RegexOptions.IgnoreCase);
```

```
the result would be -
  2 items found:
    foo
    FOO
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.6 CxList.FindByRegexExt Method (string, string, CxRegexOptions)

Syntax

```
CxQL
public CxList FindByRegexExt(string pattern, string fileMask, CxRegexOptions
cxOptions)
```

Parameters

pattern

Regular expression pattern

fileMask

File mask for search. Control characters "*" and "?" are supported.

For example: "*.*" looks in all files and "*.aspx" looks in aspx files.

cxOptions

An enum matching the relevant CxRegexOptions which are:

None, SearchInComments, DoNotSearchInStringLiterals, AllowOverlaps and

SearchOnlyInComments

Return Value

A list of matches for given regular expression in chosen project files including or excluding results in comments with regex build with specified options.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

CXQL

```
This example demonstrates the CxList.FindByRegexExt() method.
The input source code is:
```

```
int a = 5;
if (a > 3)
    foo(a);
else
    FOO(a);
```

```
// foo(a)
/* foo */

result = All.FindByRegexExt(@"(\s)?foo", "*.cs", RegexOptions.IgnoreCase);

the result would be -
  2 items found:
    foo
    FOO
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.7 CxList.FindByRegexExt Method (string, string, CxRegexOptions, RegexOptions)

Syntax

```
CxQL
public CxList FindByRegexExt(string pattern, string fileMask = " *.*",
CxRegexOptions cxOptions = CxRegexOptions.None, RegexOptions regularOptions
= RegexOptions.None)
```

Parameters

expression

Regular expression pattern

fileMask – optional

Default value: " *.*".

File mask for search. Control characters "*" and "?" are supported.

For example: " *.*" looks in all files and "*.aspx" looks in aspx files.

cxOptions – optional

An enum matching the relevant CxRegexOptions which are:

[None](#), [SearchInComments](#), [DoNotSearchInStringLiterals](#), [AllowOverlaps](#) and
[SearchOnlyInComments](#)

regularOptions – optional

Default value: RegexOptions.None.

Options for regular expression build from first parameter - **pattern**

Return Value

A list of matches for given regular expression in choosen project files including or excluding results in comments with regex build with specified options.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

```
CXQL
```

```
This example demonstrates the CxList.FindByRegexExt() method.  
The input source code is:  
int a = 5;  
if (a > 3)  
    foo(a);  
else  
    FOO(a);  
  
// foo(a)  
/* foo */  
  
result = All.FindByRegexExt(@"(\s)?foo", "*.cs", false,  
RegexOptions.IgnoreCase);  
  
the result would be -  
    2 item found:  
        foo  
        FOO
```

Version Information

Supported from version 7.1.8 and 7.1.6HF5

4.67.8 CxList.FindByRegexExt Method (string, List<string>, bool, CxRegexOptions, RegexOptions)

Syntax

```
CxQL  
public CxList FindByRegexExt(string expression, List<string> fileMaskList,  
bool searchInComments = true, CxRegexOptions cxOptions =  
CxRegexOptions.SearchInComments, RegexOptions regularOptions =  
RegexOptions.None)
```

Parameters

expression

Regular expression pattern

fileMaskList

List of File masks for search. Control characters "*" and "?" are supported.

For example: "*.*" looks in all files and "*.aspx" looks in aspx files.

searchInComments – optional

Default value: true.

Allow or not search in comments

cxOptions - optional

An enum matching the relevant CxRegexOptions which are:

None, SearchInComments, DoNotSearchInStringLiterals, AllowOverlaps and

SearchOnlyInComments

regularOptions – optional

Default value: RegexOptions.None.

Options for regular expression build from first parameter - **pattern**

Return Value

A list of matches for given regular expression in chosen project files including or excluding results in comments with regex build with specified options.

Remarks

The return value may be empty (Count = 0).

Default values relevant only from version 7.1.8.

Example

The following code example shows how you can use the FindByRegexExt method.

CxQL

This example demonstrates the CxList.FindByRegexExt() method.
The input source code is:

```
int a = 5;
if (a > 3)
    foo(a);
else
    FOO(a);
// foo(a)
/* foo */
```

```
result = All.FindByRegexExt(@"(\s)?foo", new List<string>{ "*.cs", "*.js"}, false,
CxRegexOptions.SearchInComments, RegexOptions.IgnoreCase);
```

```
the result would be -
  2 item found:
    foo
    FOO
```

Version Information

Supported from version 8.0.0

4.68 CxList.FindByReturnType Method (string)

Returns a CxList which is a subset of this instance and its elements are of the specified type.

Syntax

```
CxQL  
public CxList FindByReturnType(String Type, bool  
stripPointerAndRefFromReturnType = true)
```

Parameters

Type

The type of the objects to be found

stripPointerAndRefFromReturnType

true – the result will include methods that return Type* as well as methods that return Type

Return Value

A subset of this instance and its elements are of the specified return type.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByReturnType method.

```
CxQL  
  
This example demonstrates the CxList.FindByReturnType() method.  
The input source code is:  
public class a  
{  
    int bla()  
    {  
        int b, a = 5;  
        if (a == 33)  
            b = 6;  
        return b;  
    }  
}  
result = All.FindByReturnType ("int");  
the result would be -  
1 items found:  
    bla() (in int bla())
```

Version Information

Supported from v1.8.1

4.69 CxList.FindByShortName Method (string)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified string.

Syntax

```
CxQL  
public CxList FindByShortName(string Name)
```

Parameters

Name

The short name of the objects to look for. Prefix and postfix wildcard (*) are supported.

Return Value

A subset of this instance and its elements are the ones which their name is the specified string.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByShortName method.

```
CXQL  
  
This example demonstrates the CxList.FindByShortName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByShortName("Method");  
  
the result would be -  
1 item found:  
Method ( in b = a.Method() )
```

Version Information

Supported from v1.8.1

4.70 CxList.FindByShortName Method (string, bool)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria.

Syntax

```
CxQL  
public CxList FindByName(string ShortName, bool caseSensitive)
```

Parameters

ShortName

Contains the short name of the objects. Prefix and postfix wildcard (*) are supported.

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria. Where the caseSensitive value can be true for case sensitive and false for case insensitive.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByShortName method.

```
CxQL  
This example demonstrates the CxList.FindByShortName() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
result = All.FindByShortName("method", true);  
the result would be -  
    0 items found  
  
result = All.FindByShortName("method", false);  
  
the result would be -  
    1 item found:  
    a.Method (in b = a.Method() )
```

Version Information

Supported from v1.8.1

4.71 CxLis.FindByShortNames Method (List<string>)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified list of strings.

Syntax

```
CxQL  
public CxList FindByShortNames(List<string> nodeNames)
```

Parameters

nodeNames

The short names of the objects to look for. Prefix and postfix wildcard (*) are supported.

Return Value

A subset of this instance and its elements are the ones which their name listed in specified list of strings.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0). Works efficient if wildcard not present.

Example

The following code example shows how you can use the FindByShortNames method.

```
CXQL  
  
This example demonstrates the CxList.FindByShortNames() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
c = a.Method1()  
  
result = All.FindByShortNames(new List<string> {"Method", "Method1"});  
  
the result would be -  
2 item found:  
    Method ( in b = a.Method() )  
    Method1 ( in c = a.Method1() )
```

Version Information

Supported from v7.1.8

4.72 CxList.FindByShortNames Method (List<string>, bool)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria.

Syntax

```
CxQL  
public CxList FindByNames(List<string> nodeNames, bool caseSensitive)
```

Parameters

nodeNames

Contains the short name of the objects. Prefix and postfix wildcard (*) are supported.

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria. Where the caseSensitive value can be true for case sensitive and false for case insensitive.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0). Works efficient if wildcard not present.

Example

The following code example shows how you can use the FindByShortName method.

```
CxQL  
  
This example demonstrates the CxList.FindByShortNames() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
c = a.method1();  
  
result = All.FindByShortNames(new List<string> {"method","Method1"}, true);  
the result would be -  
1 items found  
c = a.method1();  
  
result = All.FindByShortNames(new List<string> {"method","Method1"}, false);  
  
the result would be -  
2 item found:
```

```
a.Method (in b = a.Method() )  
a.method1 (in c = a.method1 () )
```

Version Information

Supported from v7.1.8

4.73 CxList.FindByShortName Method (CxList)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified string.

Syntax

```
CxQL  
public CxList FindByShortName(CxList nodesList)
```

Parameters

nodesList

The short name of the objects to look for. Prefix and postfix wildcard (*) are supported.

Return Value

A subset of this instance and its elements are the ones which their name is the specified string.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByShortName method.

```
CxQL  
This example demonstrates the CxList.FindByShortName() method.  
The input source code is:  
  
class Program  
{  
    static void Main(string[] args)  
    {  
        Customer c = new customer();  
    }  
}  
class Customer{}  
class User{}  
CxList classes = All.FindByType(typeof(ClassDecl));  
CxList types = All.FindByType(typeof(TypeRef));  
CxList classeswithInstances = classes - classes.FindByShortName(types);  
  
the result would be -  
3 item found:  
    Customer ( in class Customer{ })  
    Program ( in class Program )  
    User ( in class User{ })
```

Version Information

Supported from v1.8.1

4.74 CxList.FindByShortName Method (CxList, bool)

Returns a CxList which is a subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria.

Syntax

```
CxQL  
public CxList FindByName(CxList nodesList, bool caseSensitive)
```

Parameters

nodesList

Contains the short name of the objects. Prefix and postfix wildcard (*) are supported.

caseSensitive

Boolean which indicates to the search to be (or not) case sensitive.

Return Value

A subset of this instance and its elements are the ones which their short name is the specified string, according to the specified comparison criteria. Where the caseSensitive value can be true for case sensitive and false for case insensitive.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByShortName method.

CxQL

```
This example demonstrates the CxList.FindByShortName() method.  
The input source code is:
```

```
class Program  
{  
    static void Main(string[] args)  
    {  
        Customer c = new customer();  
    }  
}  
class Customer{}  
class User{}  
  
CxList classes = All.FindByType(typeof(ClassDecl));  
CxList types = All.FindByType(typeof(TypeRef));  
CxList classeswithInstances = classes - classes.FindByShortName(types,  
true);
```

```
the result would be -
    the same as FindByShortName(CxList nodesList)

CxList classes = All.FindByType(typeof(ClassDecl));
CxList types = All.FindByType(typeof(TypeRef));
CxList classeswithInstances = classes - classes.FindByShortName(types,
false);

the result would be -
    2 item found:
        Program ( in class Program)
        User ( in class User{ })
```

Version Information

Supported from v1.8.1

4.75 CxList.FindByTypeModifiers

Method (TypeSignednessModifiers, TypeSizeModifiers)

Returns a CxList which is a subset of this instance and its elements are of the specified type modifiers of code element.

Syntax

```
CxQL  
public CxList FindByTypeModifiers(TypeSignednessModifiers TypeSignedness,  
TypeSizeModifiers TypeSize)
```

Parameters

TypeSignedness

The type of the objects to be found. It can receive the following alternative values:

- [TypeSignednessModifiers.Unknown](#)
- [TypeSignednessModifiers.Signed](#)
- [TypeSignednessModifiers.Unsigned](#)

TypeSize

The type of the objects to be found. It can receive the following alternative values:

- [TypeSignednessModifiers.Default](#)
- [TypeSignednessModifiers.Short](#)
- [TypeSignednessModifiers.Long](#)
- [TypeSignednessModifiers.LongLong](#)

Return Value

A subset of this instance which elements type contains both modifiers provided.

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CxQL  
  
This example demonstrates the CxList.FindByTypeModifiers() method.  
The input source code is:  
unsigned long int a;  
int b;  
b = a++;  
  
result = All.FindByTypeModifiers (TypeSignednessModifiers.Unsigned,  
TypeSizeModifiers.Long);  
the result would be -  
3 items found:  
int (in unsigned long int a)  
a (in unsigned long int a)  
a (in b = a++)
```

Version Information

Supported from v8.8.0

4.76 CxList.FindByTypeModifiers Method (TypeSignednessModifiers)

Returns a CxList which is a subset of this instance and its elements are of the specified type modifiers of code element.

Syntax

```
CxQL  
public CxList FindByTypeModifiers(TypeSignednessModifiers TypeSignedness,  
TypeSizeModifiers TypeSize)
```

Parameters

TypeSignedness

The type of the objects to be found. It can receive the following alternative values:

- `TypeSignednessModifiers.Unknown`
- `TypeSignednessModifiers.Signed`
- `TypeSignednessModifiers.Unsigned`

Return Value

A subset of this instance which elements type contains the modifier provided.

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CxQL  
  
This example demonstrates the CxList.FindByTypeModifiers() method.  
The input source code is:  
unsigned long int a;  
int b;  
b = a++;  
  
result = All.FindByTypeModifiers (TypeSignednessModifiers.Unsigned);  
the result would be -  
3 items found:  
    int (in unsigned long int a)  
    a (in unsigned long int a)  
    a (in b = a++)
```

Version Information

Supported from v8.8.0

4.77 CxList.FindByTypeModifiers Method (TypeSizeModifiers)

Returns a CxList which is a subset of this instance and its elements are of the specified type modifiers of code element.

Syntax

```
CxQL  
public CxList FindByTypeModifiers(TypeSignednessModifiers TypeSignedness,  
TypeSizeModifiers TypeSize)
```

Parameters

TypeSize

The type of the objects to be found. It can receive the following alternative values:

- `TypeSignednessModifiers.Default`
- `TypeSignednessModifiers.Short`
- `TypeSignednessModifiers.Long`
- `TypeSignednessModifiers.LongLong`

Return Value

A subset of this instance which elements type contains the modifier provided.

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CXQL  
  
This example demonstrates the CxList.FindByTypeModifiers() method.  
The input source code is:  
unsigned long int a;  
int b;  
b = a++;  
  
result = All.FindByTypeModifiers (TypeSizeModifiers.Long);  
the result would be -  
3 items found:  
    int (in unsigned long int a)  
    a (in unsigned long int a)  
    a (in b = a++)
```

Version Information

Supported from v8.8.0

4.78 CxList.FindByType Method (Type)

Returns a CxList which is a subset of this instance and its elements are of the specified type of code element.

Syntax

```
CxQL  
public CxList FindByType(Type TypeName)
```

Parameters

TypeName

The type of the objects to be found

Return Value

A subset of this instance and its elements are of the specified type of code element.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CxQL  
  
This example demonstrates the CxList.FindByType() method.  
The input source code is:  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByType (typeof(MemberAccess));  
the result would be -  
2 items found:  
a.DataMember (in a.DataMember = 3)  
a.Method (in b = a.Method())
```

Version Information

Supported from v1.8.1

4.79 CxList.FindByType Method (string)

Returns a CxList which is a subset of this instance and its elements are of the specified type.

Syntax

```
CxQL  
public CxList FindByType(String Type)
```

Parameters

Type

The type of the objects to be found

Return Value

A subset of this instance and its elements are of the specified type.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

CxQL

```
This example demonstrates the CxList.FindByType() method.
```

```
The input source code is:
```

```
MyClass a;
```

```
int b;
```

```
a.DataMember = 3;
```

```
b = a.Method();
```

```
result = All.FindByType ("MyClass");
```

```
the result would be -
```

```
3 items found:
```

```
    a (in MyClass a)
```

```
    a (in a.DataMember = 3)
```

```
    a (in b = a.Method())
```

Version Information

Supported from v1.8.1

4.80 CxList.FindByType Method (string, bool)

Returns a CxList which is a subset of this instance and its elements are of the specified type.

Syntax

```
CxQL  
public CxList FindByType(String Type, bool CaseSensitive)
```

Parameters

Type

The type of the objects to be found

CaseSensitive

Ignore case true/false

Return Value

A subset of this instance and its elements are of the specified type.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CxQL  
  
This example demonstrates the CxList.FindByType() method.  
The input source code is:  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
result = All.FindByType ("MyClass",true);  
the result would be -  
3 items found:  
a (in MyClass a)  
a (in a.DataMember = 3)  
a (in b = a.Method())
```

Version Information

Supported from v1.8.1

4.81 CxList.FindByTypes Method (string[])

Returns a CxList which is a subset of this instance and its elements are of the specified type.

Syntax

```
CxQL  
public CxList FindByType(String[] Types)
```

Parameters

Types

The types of the objects to be found

Return Value

A subset of this instance and its elements are of the specified types.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CXQL  
  
This example demonstrates the CxList.FindByType() method.  
The input source code is:  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
  
String[] arr = new String[]{"MyClass","int"};  
result = All.FindByTypes(arr);  
the result would be -  
6 items found:  
a (in MyClass a)  
a (in a.DataMember = 3)  
a (in b = a.Method())  
b (in int b)  
b (in b = a.Method())  
MyClass (in MyClass a)
```

Version Information

Supported from v1.8.1

4.82 CxList.FindByTypes Method (string[], bool)

Returns a CxList which is a subset of this instance and its elements are of the specified type.

Syntax

```
CxQL  
public CxList FindByType(String[] Types, bool caseSensitive)
```

Parameters

Types

The types of the objects to be found

CaseSensitive

Ignore case true/false

Return Value

A subset of this instance and its elements are of the specified types.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the FindByType method.

```
CxQL  
This example demonstrates the CxList.FindByType() method.  
The input source code is:  
  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
String[] arr = new String[]{"MyClass","int"};  
result = All.FindByTypes(arr,false);  
the result would be -  
6 items found:  
a (in MyClass a)  
a (in a.DataMember = 3)  
a (in b = a.Method())  
b (in int b)  
b (in b = a.Method())  
MyClass (in MyClass a)
```

Version Information

Supported from v7.1.8

4.83 CxList.FindDefinition Method (CxList)

Returns a CxList which is a subset of "this" instance, with elements that are the definition locations of the first element in the given CxList.

Syntax

```
CxQL  
public CxList FindDefinition(CxList items)
```

Parameters

Items

Items whose definition to be found.

Return Value

A subset of "this" instance, with elements that are the definition locations of the first element in the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindDefinition() method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = a;  
  
result = All.FindDefinition(All.FindByName("*b*"));  
  
The result would consist of 1 item:  
    b (in int b, a = 5)
```

Version Information

Supported from v1.8.1

4.84 CxList.FindInitialization Method (CxList)

Returns a CxList which is a subset of "this" instance and the elements are the initialization values of the elements from the given CxList.

Syntax

```
CxQL  
public CxList FindInitialization(CxList declarators)
```

Parameters

Declarators

A CxList of declarators.

Return Value

A subset of "this" instance whose elements are the initialization values of the given CxList elements.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.FindInitialization() method.  
The input source code is:  
  
int b = 5;  
  
CxList declarators = All.FindByType(typeof(Declarator));  
result = All.FindInitialization(declarators);  
  
The result would consist of 1 item:  
5
```

Version Information

Supported from v1.8.1

4.85 CxList.FindInScope Method

(CxList, CxList)

Returns a CxList which is a subset of "this" instance with the elements inside the scopes defined by the start nodes CxList and the end nodes CxList.

Syntax

```
CxQL  
public CxList FindInScope(CxList StartNodes, CxList EndNodes)
```

Parameters

StartNodes

the nodes that define the start of the scope.

EndNodes

the nodes that define the end of the scope.

Return Value

all nodes found inside the given scope.

Example

This example demonstrates the `CxList.FindInScope(CxList StartNodes, CxList EndNodes)` method.

The input source code is:

```
@{ Html.BeginForm(); } //Defines the start of the scope  
@Html.AntiForgeryToken();  
@{ Html.EndForm(); } //Defines the end of the scope
```

```
CxList BeginFormMethods = All.FindByShortName("BeginForm");  
CxList EndFormMethods = All.FindByShortName("EndForm");  
result = All.FindInScope(BeginFormMethods, EndFormMethods);
```

the result would consist of 1 item:

```
AntiForgeryToken (@Html.AntiForgeryToken;)
```

The purpose of the query is to find anything that is contained inside a specific scope.

Version Information

Supported from 8.5.0

4.86 CxList.GetAncOfType Method (Type)

Returns a CxList with all the elements that are CxDOM first ancestor of the calling CxList and which are of type t. First ancestor means that it searches upward in the CxDOM graph until the first ancestor matching the condition (type t), and NOT that it searches only for fathers

Syntax

```
CxQL  
public CxList GetAncOfType(Type t)
```

Parameters

The type of DOM object the methods looks for

Return Value

Returns a CxList with all the CxDOM elements of type t, which are first ancestor, of some element in the calling CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

This command does not return a subset of the CxList, but a subset of All.

Example

The following code example shows how you can use the GetAncOfType method.

```
CxQL  
This example demonstrates the CxList.GetAncOfType() method.  
The input source code is:  
  
if (a>b)  
{  
    c=100;  
}  
else  
{  
    if(a<100)  
    {  
        d=200;  
    }  
}  
  
result = All.FindByName("d"). GetAncOfType(typeof(IfStmt));  
the result would be -  
1 item found:  
if (in if(a<100))
```

Version Information

Supported from v2.0.5

4.87 CxList.GetArrayOfNodeIds Method

()

Returns a ArrayList which is a set of all elements IDs All this CxList.

Syntax

```
CxQL  
public ArrayList GetArrayOfNodeIds()
```

Parameters

None

Return Value

ArrayList which is a set of all elements IDs All this CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Example

The following code example shows how you can use the FindByReturnType method.

```
CxQL  
  
This example demonstrates the CxList.GetArrayOfNodeIds() method.  
The input source code is:  
public class a  
{  
void foo(){  
MyClass a;  
int b;  
a.DataMember = 3;  
b = a.Method();  
}  
}  
CxList ls = All;  
foreach(int NodeId in ls.GetArrayOfNodeIds())  
{  
if(NodeId !=1)  
{  
result = All.FindById(NodeId);  
}  
}
```

Version Information

Supported from : v1.8.1

4.88 CxList.GetBlocksOfIfStatements Method (bool)

Returns a CxList with all the true/false blocks of the if statements inside the calling CxList according the the provided boolean parameter. The true block of an if statement is the block which is ran if the condition is verified, whereas the false block is the else block (if it exists).

Syntax

```
CxQL  
public CxList GetBlocksOfIfStatements(Boolean block)
```

Parameters

A Boolean describing wether you want to retrieve the true or false blocks of the if statements inside the calling CxList.

Return Value

Returns a CxList containing all the true/false blocks of the if statements contained in the calling CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

This command does not return a subset of the CxList, but a subset of All.

Example

The following code example shows how you can use the GetBlocksOfIfStatements method.

```
CxQL  
  
This example demonstrates the CxList.GetBlocksOfIfStatements(block) method.  
The input source code is:  
  
int a = 5;  
if (a > 3)  
{  
    a = 4;  
}  
else if(a > 2)  
{  
    a = 2;  
}  
else  
{  
    a = 8;  
}  
  
result = All.GetBlocksOfIfStatements(true);  
  
The result would consist of 2 items: the braces after if(a>3) (true block  
of the if), and the braces after the else if (true block of the if).
```

```
result = All.GetBlocksOfIfStatements(false);
```

This query ran on the same sample code would return the `if(a>2)` (false block of the else in else if), and the braces after the else.

Version Information

Supported from v8.5.0

4.89 CxList.GetBlocksOfIterationStatements Method ()

Returns a CxList with the blocks of all the iterations contained in the calling CxList.

Syntax

```
CxQL  
public CxList GetBranchesOfTernaryExpression(Boolean branch)
```

Parameters

None.

Return Value

Returns a CxList containing all the blocks of the iterations in the calling CxList.

Remarks

The return value may be empty (Count = 0).

This command does not return a subset of the CxList, but a subset of All.

Example

The following code example shows how you can use the GetBlocksOfIterationStatements method.

CxQL

```
This example demonstrates the CxList.GetBlocksOfIterationStatements()  
method.
```

```
The input source code is:
```

```
while(condition)  
{  
    a = 1;  
}  
for(int i=0; i<10; i++)  
{  
    // code  
}
```

```
result = All.GetBlocksOfIterationStatements();
```

```
The result would consist of 2 item: the 2 opening braces in the code.
```

Version Information

Supported from v8.5.0

4.90 CxList.GetBranchesOfTernaryExpressions Method (bool)

Returns a CxList with all the true/false branches of the ternary expressions inside the calling CxList according to the provided boolean parameter. The true branch of a ternary expression is the value given if the condition is true, whereas the false block is the value given if the condition is false.

Syntax

```
CxQL  
public CxList GetBranchesOfTernaryExpression(Boolean branch)
```

Parameters

A boolean describing whether you want to retrieve the true or false branches of the ternary expressions inside the calling CxList.

Return Value

Returns a CxList containing all the true/false branches of the ternary expressions in the calling CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

This command does not return a subset of the CxList, but a subset of All.

Example

The following code example shows how you can use the GetBranchesOfTernaryExpressions method.

CxQL

```
This example demonstrates the  
CxList.GetBranchesOfTernaryExpressions(branch) method.  
The input source code is:
```

```
int a = someCondition ? 1:0;
```

```
result = All.GetBranchesOfTernaryExpressions(true);
```

```
The result would consist of 1 item: the number 1.
```

```
result = All.GetBranchesOfTernaryExpressions(false);
```

```
The result would consist of 1 item: the number 0.
```

Version Information

Supported from v8.5.0

4.91 CxList.GetByAncs Method (CxList)

Returns all elements in this instance that is a CxDOM descendant of an element of the parameter.

Syntax

```
CxQL  
public CxList GetByAncs(CxList ancs)
```

Parameters

ancs

The Ancestors whose descendants are to be returned

Return Value

Returns all elements in this instance that descends any of the elements in the parameter

Example

The following code example shows how you can use the GetByAncs method.

```
CxQL  
  
This example demonstrates the CxList.GetByAncs() method.  
The input source code is:  
public notmuch (boolean tf)  
{  
    boolean localboolean = tf;  
}  
  
result = All.GetByAncs(All.FindByName("notmuch"));  
  
6 items found:  
notmuch  
boolean (in Boolean tf)  
tf  
boolean  
localboolean  
=  
tf (in localboolean=tf)
```

Version Information

Supported from v2.0.5

4.92 CxList.GetByBinaryOperator Method (BinaryOperator)

Returns a CxList which is a subset of this instance and its elements are binary expressions with a given binary operator.

Syntax

```
CxQL  
public CxList GetByBinaryOperator(BinaryOperator opr)
```

Parameters

opt

Enum type of binary operators.

Return Value

A subset of this instance with binary expressions which have a given binary operator.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetByBinaryOperator method.

CxQL

```
This example demonstrates the CxList.GetByBinaryOperator() method.  
The input source code is:
```

```
int i;  
if(i < 1)  
    ...
```

```
result = All.GetByBinaryOperator(BinaryOperator.LessThan);
```

```
the result would be -  
  1 item found:  
  <
```

Version Information

Supported from v1.8.1

4.93 CxList.GetByClass Method (CxList)

Returns all elements in "this" instance that belong to any of the classes in the parameter.

Syntax

```
CxQL  
public int GetByClass(CxList classes)
```

Parameters

classes

The classes whose elements to be returned

Return Value

Returns all elements in this instance that belong to any of the classes in the parameter

Example

```
CxQL
```

```
This example demonstrates the CxList.GetByClass() method.  
The input source code is:
```

```
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
class c12  
{  
    void foo2()  
    {  
        int c = 3;  
    }  
}
```

```
result = All.GetByClass(All.FindByName("*.c11")).FindByName("3");
```

```
The result would consist of 1 item found:
```

```
3 (in int a = 3)
```

```
Notice that 3 (in int c = 3) doesn't appear in the results, since it is not  
in the "c11" class
```

4.94 CxList.GetByMethod Method (CxList)

Returns all elements in this instance that belong to any of the methods in the parameter

Syntax

```
CxQL  
public int GetByMethod(CxList methods)
```

Parameters

methods

The methods whose elements to be returned

Return Value

Returns all elements in this instance that belong to any of the methods in the parameter

Example

The following code example shows how you can use the GetByMethod method.

```
CXQL  
  
This example demonstrates the CxList.GetByMethod() method.  
The input source code is:  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
    void foo2()  
    {  
        int c = 3;  
    }  
}  
  
result = All.GetByMethod(All.FindByName("foo2")).FindByName("3");  
  
1 item found:  
    3 (in int c = 3)  
Notice that 3 (in int a = 3) doesn't appear in the results, since it is not  
in the "foo2" method
```

Version Information

Supported from v2.0.5

4.95 CxList.GetClass Method (CxList)

Returns the classes of this instance containing the objects in the parameter.

Syntax

```
CxQL  
public CxList GetClass(CxList elements)
```

Parameters

elements

The elements whose classes to be returned

Return Value

Returns the classes of this instance containing the objects in the parameter.

Example

The following code example shows how you can use the GetClass method.

```
CxQL  
  
This example demonstrates the CxList.GetClass() method.  
The input source code is:  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
  
result = All.GetClass(All.FindByName ("5"));  
  
1 item found:  
    c11 (in class c11)
```

Version Information

Supported from v2.0.5

4.96 CxList.GetCxListByPath Method ()

Create enumerator on CxList that enumerate on all existing paths.

Syntax

```
CxQL  
public IEnumerable<CxList> GetCxListByPath()
```

Parameters

No parameters

Exceptions

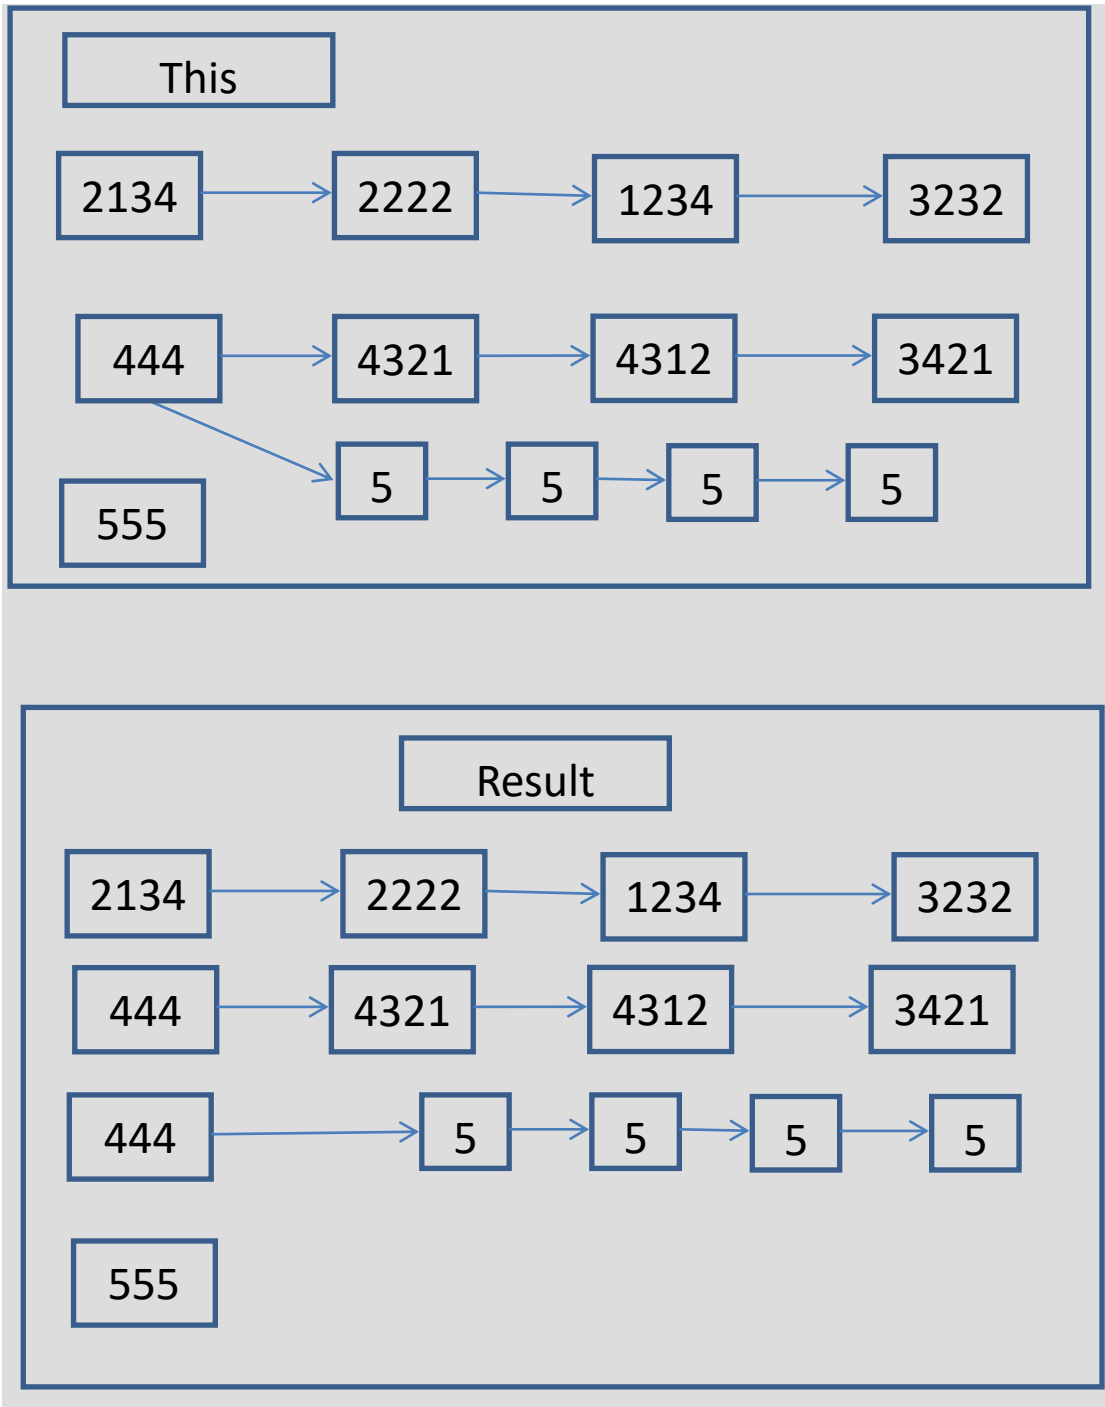

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

None

Example

```
CxQL  
  
This example demonstrates the IEnumerable<CxList> GetCxListByPath() method.  
  
foreach (CxList thisCxList in this.GetCxListByPath())  
{  
    // thisCxList shall include one node and one path. If in "this" exists  
nodes without  
    // pathes than thisCxList will have only one node.  
}
```

Version Information

Supported from v7.1.3

4.97 CxList.GetEnumerator Method ()

Return IEnumerator of CxList.Data

Syntax

```
CxQL  
public IEnumerator GetEnumerator()
```

Parameters

none

Return Value

Enumerator of CxList.Data.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

Not in use (deprecated). A simpler implementation is by:

```
foreach (CxList cxItem in resultList)  
{  
:  
}
```

Example

```
CxQL  
  
This example demonstrates the GetEnumerator, cxLog.WriteDebugMessage and  
GetFirstGraph method.  
The input source code is:  
  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
  
IEnumerator ieNum = All.GetEnumerator();  
bool finish = false;  
int i = 1;  
while (!finish)  
{  
    if (!ieNum.MoveNext())  
    {  
        finish = true;  
    }  
    else  
    {  
        CxList curr = (CxList) ieNum.Current;
```

```

    if (curr.GetFirstGraph() != null)
    {
        cxLog.WriteDebugMessage ("#" + i.ToString() +
            " curr name = " + curr.GetName() + " type = " +
            curr.GetFirstGraph().GraphType.ToString());
        i++;
    }
}
}
}

```

the result would be on DebugMessage tab in CxAudit program

Query	Results	Comments	Debug Messages
Query Name	Debug Message

Version Information

Supported from v1.8.1

4.98 CxList.GetFathers Method ()

Returns a CxList which contains the direct fathers of the elements of “this” instance.

Syntax

```
CxQL  
public CxList GetFathers ()
```

Return Value

A CxList which contains the direct fathers of the element of “this” instance.

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.GetFathers () method.  
The input source code is:  
  
int b, a = 5;  
if (a > 3)  
    b = 6;  
  
CxList six = All.FindByName("6");  
result = six.GetFathers();  
  
the result would consist of 1 item found:  
=
```

4.99 CxList.GetFinallyClause Method (CxList)

Returns a CxList which is a subset of this instance and its elements are finally clauses of the specified CxList of try statements.

Syntax

```
CxQL  
public CxList GetFinallyClause (CxList TryList)
```

Parameters

TryList

CxList of try statements.

Return Value

A subset of this instance with finally clauses.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetFinallyClause method.

```
CxQL  
This example demonstrates the CxList.GetFinallyClause() method.  
The input source code is:
```

```
int j;  
try  
{  
    int i = 0;  
    j = 1 / i;  
}  
finally  
{  
    j = 1;  
}
```

```
CxList Try = All.FindByType(typeof(TryCatchFinallyStmt));  
result = All.GetFinallyClause(Try);  
the result would be -  
1 item found:  
finally
```

Version Information

Supported from v1.8.1

4.100 CxList.GetFirstGraph Method ()

Returns a first data element in requested CxList. Using to get internal data of first object in requested CxList

Syntax

```
CxQL  
public CSharpGraph GetFirstGraph()
```

Parameters

none

Return Value

A first element in Data. If CxList empty return null.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

N/A

Example

```
CxQL  
  
This example demonstrates the CxList.GetFirstGraph() method.  
The input source code is:  
  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
result = All.FindByShortName("foo");  
if (result.Count > 0)  
    cxLog.WriteDebugMessage(result.GetFirstGraph().ShortName);  
  
the result would be on DebugMessage tab in CxAudit program  
foo
```

Version Information

Supported from v1.8.1

4.101 CxList.GetFollowingStatements Method ()

Returns a CxList of the statements that are directly following all the statements of the calling CxList and in the same statement collection.

Syntax

```
CxQL  
public CxList GetFollowingStatements()
```

Parameters

None.

Return Value

Returns a CxList containing all the statements that are following the statements in the calling CxList.

Remarks

The return value may be empty (Count = 0).

This command does not return a subset of the CxList, but a subset of All.

Example

The following code example shows how you can use the GetFollowingStatements method.

CxQL

```
This example demonstrates the CxList.GetFollowingStatements() method.  
The input source code is:
```

```
if (a > 3)  
{  
    a = 4;  
}  
if(a != 4)  
{  
    a = 0;  
    b = 5;  
}  
c = 2;  
d = 3;
```

```
result = All.GetFollowingStatements();
```

```
The result would consist of 2 items: the assignment b=5 (following a=0),  
and d=3 (following c=2).
```

```
The assignment a=4 doesn't have any following statement in its scope.
```

Version Information

Supported from v8.5.0

4.102 CxList.GetMembersOfTarget Method ()

Returns a CxList with all found members of the specified target.

Syntax

```
CxQL  
public CxList GetMembersOfTarget()
```

Return Value

A CxList with members of a given target.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetMembersOfTarget method.

CxQL

```
This example demonstrates the CxList.GetMembersOfTarget() method.  
The input source code is:
```

```
StreamWriter sw = new StreamWriter();  
sw.Write("");
```

```
CxList swriter = All.FindByType("StreamWriter");  
result = swriter.GetMembersOfTarget();
```

```
the result would be -  
  1 item found:  
  write
```

Version Information

Supported from v1.8.1

4.103 CxList GetRightmostMember()

Returns a CxList with the rightmost members of the specified target.

Syntax

```
CxQL  
public CxList GetRightmostMember()
```

Return Value

A CxList with the rightmost members of a given target.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetRightmostMember method.

```
CxQL  
  
This example demonstrates the CxList.GetRightmostMember() method.  
The input source code is:  
  
int i = foo().Bar().a.b;  
  
CxList foo = All.FindByName("foo");  
result = foo.GetRightmostMember();  
  
the result would be -  
  1 item found:  
  b
```

Version Information

Supported from v8.0

4.104 CxList GetLeftmostTarget()

Returns a CxList with leftmost target of the specified member.

Syntax

```
CxQL  
public CxList GetLeftmostTarget()
```

Return Value

A CxList with the leftmost target of a given member.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetRightmostMember method.

CxQL

```
This example demonstrates the CxList.GetLeftmostTarget() method.  
The input source code is:
```

```
int i = foo().Bar().a.b;  
  
CxList b = All.FindByName("b");  
result = b.LeftmostTarget();
```

```
the result would be -  
  1 item found:  
    foo
```

Version Information

Supported from v8.0

4.105 CxList.GetMembersWithTargets Method ()

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: **target.member**) and have a direct target (i.e. they are the member).

Syntax

```
CxQL  
public CxList GetMemberswithTargets()
```

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct target.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetMembersWithTargets method.

```
CXQL  
  
This example demonstrates the CxList.GetMemberswithTargets() method.  
The input source code is:  
  
int num = 55;  
string Str = num.ToString().ToUpper().PadLeft(5, ' ');  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
result = methods.GetMemberswithTargets();  
  
the result would be -  
3 items found:  
    PadLeft, ToUpper, ToString in  
num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.106 CxList.GetMembersWithTargets Method (CxList)

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: `target.member`) and have a direct target in the CxList parameter "targets".

Syntax

```
CxQL  
public CxList GetMemberswithTargets(CxList targets)
```

Parameters

targets - CxList of DOM objects which might be the target(s) of elements in "this"

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct target in "targets" parameter

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

If targets is null – returns an empty CxList

Example

The following code example shows how you can use the GetMembersWithTargets method.

```
CXQL  
  
This example demonstrates the CxList.GetMemberswithTargets() method.  
The input source code is:  
  
int num = 55;  
string Str = num.ToString().ToUpper().PadLeft(5, ' ');  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
CxList num = All.FindByShortName("num");  
result = methods.GetMemberswithTargets(num);  
  
the result would be -  
1 item found:  
ToString in num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.107 CxList.GetMembersWithTargets

Method (CxList, int)

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: **target.member**) and have a direct target in "targets" parameter, or a target of target, a target of a target of a target Up to depthLimit depth

Syntax

```
CxQL
public CxList GetMembersWithTargets (CxList targets, int depthLimit)
```

Parameters

targets - CxList of DOM objects which might be the target(s) of elements in "this", or the target of a target of this...
depthLimit - the number of iterations to look for targets

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct target.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

If targets is null - returns an empty CxList

Example

The following code example shows how you can use the GetMembersWithTargets method.

```
CxQL

This example demonstrates the CxList.GetMembersWithTargets() method.
The input source code is:

int num = 55;
string Str = num.ToString().ToUpper().PadLeft(5, ' ');

CxList methods = All.FindByType(typeof(MethodInvokeExpr));
CxList num = All.FindByShortName("num");
result = methods.GetMembersWithTargets(num, 2);

the result would be -
2 items found:
ToString, ToUpper in num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.108 CxList.GetMethod Method (CxList)

Returns CxList which is a subset of this instance and its elements are methods of the specified CxList.

Syntax

```
CxQL  
public CxList GetMethod(CxList list)
```

Parameters

List

CxList of any DOM objects.

Return Value

A subset of this instance which contains methods of the specified CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the GetMethod method.

CxQL

```
This example demonstrates the CxList.GetMethod() method.  
The input source code is:
```

```
class C1  
{  
    void foo()  
    {  
        int i = 1;  
        i++;  
    }  
}
```

```
CxList I_var = All.FindByShortName("i");  
result = All.GetMethod(I_var);
```

```
the result would be -  
1 item found:  
foo
```

Version Information

Supported from v1.8.1

4.109 CxList.GetName Method ()

Returns a first data element name in requested CxList. Using to get internal data of first object in requested CxList

Syntax

```
CxQL  
public string GetName()
```

Parameters

none

Return Value

A name of the first element in Data. If CxList empty return null.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

None

Example

```
CXQL  
  
This example demonstrates the CxList.GetName() method.  
The input source code is:  
  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
result = All.FindByShortName("foo");  
if (result.Count > 0)  
    cxLog.WriteDebugMessage(result.GetName());  
  
the result would be on DebugMessage tab in CxAudit program  
foo
```

Version Information

Supported from v1.8.1

4.110 CxList.GetParameters Method (CxList)

Returns a CxList which is a subset of this instance and its elements are parameters of methods elements provided in CxList.

Syntax

```
CxQL  
public CxList GetParameters (CxList MethodsList)
```

Parameters

MethodList

CxList of methods.

Return Value

Returns a CxList with all the parameters, from instance CxList, of the methods in MethodsList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL
```

```
This example demonstrates the CxList.GetParameters(MethodsList) method.  
The input source code is:
```

```
foo(1, 3, i);
```

```
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
result = All.GetParameters(methods);
```

```
the result would consist of 3 items:
```

```
1,  
3,  
i
```

Version Information

Supported from v1.8.1

4.111 CxList.GetParameters Method

(CxList, int)

Returns a CxList which is a subset of instance CxList and its elements are parameters of methods elements provided in CxList.

Syntax

```
CxQL  
public CxList GetParameters (CxList MethodsList, int paramNo)
```

Parameters

MethodList

CxList of methods.

paramNo

The number of parameter to return (begins with 0)

Return Value

Returns a CxList with paramNo parameters, from instance CxList, of the methods in MethodsList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.GetParameters(MethodsList,paramNo)  
method.  
The input source code is:  
  
foo(1, 3, i);  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
result = All.GetParameters(methods, 1);  
  
the result would consist of 1 items:  
3
```

Version Information

Supported from v1.8.1

4.112 CxList.GetPathsOrigins Method ()

Returns a CxList which is a subset of instance CxList and contains end nodes of paths.

Syntax

```
CxQL  
public CxList GetPathsOrigins ()
```

Return Value

Returns CxList that contains end nodes of paths

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.GetPathsOrigins() method.  
The input source code is:  
  
public void setString (String str){  
    if (str.length >0){  
        lst.add(str);  
    }  
}  
  
CxList paths = All.DataInfluencingOn(All.FindByShortName("add"));  
result = paths.GetPathsOrigins();  
  
the result would consist of 3 items:  
    lst    (in lst.add(str);)  
    str    (in lst.add(str);)  
    str    (in (String str);)
```

4.113 CxList.GetStartAndEndNodes Method (GetStartEndNodesType)

Returns CxList which is a subset of instance CxList and contains start nodes or end nodes or both start and nodes of path or all nodes in path.

Syntax

```
CxQL  
public CxList GetStartAndEndNodes (GetStartEndNodesType type)
```

Parameters

Type

The type of nodes to be returned:

CxList.GetStartEndNodesType.StartNodesOnly

CxList.GetStartEndNodesType.EndNodesOnly

CxList.GetStartEndNodesType.StartAndEndNodes

CxList.GetStartEndNodesType.AllNodes

Return Value

Returns CxList which is a start nodes or end nodes or both start and nodes of path or all nodes in path.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.GetStartsAndEndNodes (type) method.  
The input source code is:  
  
public void setString (String str){  
    lst.add(str);  
}  
  
CxList paths = All.DataInfluencingOn(All.FindByShortName("add"));  
  
1. result =  
paths.GetStartAndEndNodes(CxList.GetStartEndNodesType.StartNodesOnly);  
the result would consist of 2 items:  
    lst    (in lst.add(str);)  
    str    (in (String str);)  
  
2. result =  
paths.GetStartsAndEndNodes(CxList.GetStartEndNodesType.EndNodesOnly);  
the result would consist of 1 items:  
    add    (in lst.add(str);)
```

```
3. result=
paths.GetStartAndEndNodes(CxList.GetStartEndNodesType.StartAndEndNodes);
the result would consist of 3 items:
    lst    (in lst.add(str);)
    str    (in (String str);)
    add    (in lst.add(str);)
4. result =
paths.GetStartAndEndNodes(CxList.GetStartEndNodesType.AllNodes);
the result would consist of 4 items:
    lst    (in lst.add(str);)
    str    (in (String str);)
    add    (in lst.add(str);)
    str    (in lst.add(str);)
5. result =
paths.GetStartAndEndNodes(CxList.GetStartEndNodesType.AllButNotStartAndEnd);
the result would consist of 2 items:
    lst    (in lst.add(str);)
    str    (in lst.add(str);)
```

Version Information

Supported from v7.1.2

4.114 CxList.GetTargetOfMembers Method ()

Returns the list of elements which are the targets from the members of "this" instance.

Syntax

```
CxQL  
public CxList GetTargetOfMembers()
```

Parameters

none

Return Value

A list of objects from which "this" instance elements are member of.

Example

```
CxQL  
  
This example demonstrates the CxList.GetTargetOfMembers() method.  
The input source code is:  
class c11  
{  
    void foo()  
    {  
        int a = obj.func();  
    }  
}  
  
result = All.FindByName("*.func").GetTargetOfMembers();  
  
The result would consist of 1 item:  
obj (in int a = obj.func())
```

4.115 CxList.GetTargetsWithMembers Method ()

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: `target.member`) and have a direct member (i.e. they are the target).

Syntax

```
CxQL  
public CxList GetTargetsWithMembers()
```

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct member.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

Example

The following code example shows how you can use the `GetTargetsWithMembers` method.

```
CXQL  
  
This example demonstrates the CxList.GetTargetsWithMembers() method.  
The input source code is:  
  
int num = 55;  
string Str = num.ToString().ToUpper().PadLeft(5, ' ');  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
result = methods.GetTargetsWithMembers();  
  
the result would be -  
2 items found:  
    ToUpper, ToString in num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.116 CxList.GetTargetsWithMembers Method (CxList)

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: `target.member`) and have a direct member in the CxList parameter "members".

Syntax

```
CxQL
public CxList GetTargetsWithMembers(CxList members)
```

Parameters

members - CxList of DOM objects which might be the member(s) of elements in "this"

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct member in members parameter.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

If members is null – returns an empty CxList

Example

The following code example shows how you can use the GetTargetsWithMembers method.

```
CXQL

This example demonstrates the CxList.GetTargetsWithMembers() method.
The input source code is:

int num = 55;
string Str = num.ToString().ToUpper().PadLeft(5, ' ');

CxList methods = All.FindByType(typeof(MethodInvokeExpr));
CxList member = All.FindByShortName("PadLeft");
result = methods.GetTargetsWithMembers(member);

the result would be -
  1 item found:
    ToUpper in num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.117 CxList.GetTargetsWithMembers

Method (CxList, int)

Returns a CxList which is a subset of "this" instance with nodes that are part of a member/target pair (typical example: **target.member**), and have a direct member in CxList parameter "members", or a member of a member... up to depth depthLimit

Syntax

```
CxQL  
public CxList GetTargetsWithMembers(CxList targets, int depthLimit)
```

Parameters

members - CxList of DOM objects which might be the member(s) of elements in "this", or the member of member of this, ...

depthLimit - the number of iterations to look for members

Return Value

Returns a CxList which is a subset of "this" instance with nodes that have a direct /chain member.

Exceptions

Exception type	Condition

Remarks

The return value may be empty (Count = 0).

If members is null - returns an empty CxList

Example

The following code example shows how you can use the GetTargetsWithMembers method.

```
CxQL  
  
This example demonstrates the CxList.GetTargetsWithMembers() method.  
The input source code is:  
  
string Str = "sample".ToString().ToUpper().PadLeft(5, ' ');  
  
CxList methods = All.FindByType(typeof(MethodInvokeExpr));  
CxList member = All.FindByShortName("PadLeft");  
result = methods.GetTargetsWithMembers(member, 2);  
  
the result would be -  
2 items found:  
ToString, ToUpper in num.ToString().ToUpper().PadLeft(5, ' ');
```

Version Information

Supported from v1.8.1

4.118 CxList.InheritsFrom Method (string)

Returns a CxList which is a subset of "this" instance and its elements are inherited from the given class name.

Syntax

```
CxQL  
public CxList InheritsFrom(string baseClassName)
```

Parameters

baseClassName

The name of the base class.

Return Value

A subset of "this" instance which elements are inherited from the given base class name.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.InheritsFrom() method.  
The input source code is:  
  
class BClass  
{  
  
}  
  
class CClass : BClass  
{  
  
}  
  
result = All.InheritsFrom("BClass");  
  
The result would consist of 1 item:  
CClass
```

Version Information

Supported from v1.8.1

4.119 CxList.InheritsFrom Method (CxList)

Returns a CxList which is a subset of "this" instance and its elements are inherited from the given CxList of classes.

Syntax

```
CxQL  
public CxList InheritsFrom(CxList baseClassList)
```

Parameters

baseClassList

The CxList of base classes.

Return Value

A subset of "this" instance which elements are inherited from the given base classes.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Comments

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.InheritsFrom() method.  
The input source code is:  
  
class BClass  
{  
  
}  
  
class CClass : BClass  
{  
  
}  
  
CxList c1 = All.FindByName("BClass");  
result = All.InheritsFrom(c1);  
  
The result would consist of 1 item:  
    CClass
```

Version Information

Supported from v1.8.1

4.120 CxList.IntersectWithNodes Method (CxList)

Returns a CxList which is a subset of paths, which are the instance CxList, that includes elements of intersected CxList.

Syntax

```
CxQL  
public CxList IntersectWithNodes (CxList intersect)
```

Parameters

intersect

intersected CxList elements

Return Value

Returns a CxList which is a subset of paths , that includes elements of intersected CxList.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
This example demonstrates the CxList.FindByPosition() method.  
The input source code is:  
  
public void setString (String str){  
    if (str.length >0){  
        lst.add(str);  
    }  
    else{  
        String otherStr ="string is empty";  
        lst.add(otherStr);  
    }  
}  
  
CxList intersect = All.FindByShortName("otherStr");  
CxList paths = All.DataInfluencingOn(All.FindByShortName("add"));  
result = paths.IntersectWithNodes(intersect);  
the result would consist of 3 items:  
all ending at add    (in lst.add(otherStr);)  
starting  
    otherStr        (in lst.add(otherStr);)  
    otherStr        (in String otherStr ="string is empty");  
    "string is empty" (in String otherStr ="string is empty");
```

Version Information

Supported from 7.1.2

4.121 CxList.ReduceFlow Method (CxList.ReduceFlowType)

Returns CxList which is a subset of instance CxList and consists of longest paths to/from destination element for CxList.ReduceFlowType.ReduceSmallFlow parameter or shortest paths to/from destination element for CxList.ReduceFlowType.ReduceBigFlow parameter.

Syntax

```
CxQL  
public CxList ReduceFlow (CxList.ReduceFlowType flowType)
```

Parameters

Type

The type of flow for reduce:

CxList.ReduceFlowType.ReduceBigFlow

CxList.ReduceFlowType.ReduceSmallFlow

Return Value

Returns CxList which is a subset of paths that consists of longest paths or shortest paths to/from destination element, depending on ReduceFlow methods parameter.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.ReduceFlow () method.  
The input source code is:  
  
ArrayList<String> lst = new ArrayList<String>();  
public void setString (String str){  
    if (str.length >0){  
        lst.add(str);  
    }  
    else{  
        String otherStr ="string is empty";  
        lst.add(otherStr);  
    }  
}  
  
CxList paths = All.DataInfluencingOn(All.FindByShortName("add"));  
  
1.result = paths.ReduceFlow(CxList.ReduceFlowType.ReduceBigFlow);  
the result would consist of 4 items:  
    all ending at add (in lst.add(otherStr);)  
    starting
```

```
lst          (in lst.add(str))  
str          (in lst.add(str))  
lst          (in lst.add(otherStr);)  
otherStr     (in lst.add(otherStr);)
```

```
2. result = paths.ReduceFlow(CxList.ReduceFlowType.ReduceSmallFlow);
```

the result would consist of 4 items:

```
all ending at add (in lst.add(otherStr);)  
starting lst      (in ArrayList<String> lst = new ArrayList<String>();)  
ending add       (in lst.add(str);)  
  
starting lst      (in lst.add(str))  
ending add       (in lst.add(otherStr);)  
  
starting str      (in (String str))  
ending add       (in lst.add(str);)  
  
starting "string is empty" (in String otherStr ="string is  
empty");  
ending add       (in lst.add(otherStr);)
```

Version Information

Supported from 7.1.2

4.122 CxList.ReduceFlowByPragma Method ()

Returns a CxList which is a subset of instance CxList and consists of shortest paths from path starting line to path end line.

Syntax

```
CxQL  
public CxList ReduceFlowByPragma ()
```

Parameters

Return Value

Returns a CxList which are shortest paths from path starting line to path end line.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.ReduceFlowByPragma () method.  
The input source code is:  
  
public void setString (){  
    String otherStr = otherStr;  
    lst.add(otherStr);  
}  
  
CxList paths = All.DataInfluencedBy(All.FindByShortName("otherStr"));  
result = paths.ReduceFlowByPragma();  
  
the result would consist of 4 items:  
starts in otherStr of (String otherStr) ends in otherStr of  
(lst.add(otherStr);)  
starts in otherStr of (= otherStr;) ends in otherStr of (String  
otherStr)  
starts in otherStr of (String otherStr) ends in add of  
(lst.add(otherStr);)  
starts in otherStr of (lst.add(otherStr);) ends in add of  
(lst.add(otherStr);)
```

Version Information

Supported from 7.1.2

4.123 CxList.SanitizeCxList Method (CxList sanitizeNodes)

Returns a CxList which is a subset of paths, which are the instance CxList, that doesn't include sanitize nodes.

Syntax

```
CxQL  
public CxList SanitizeCxList (CxList sanitizeNodes)
```

Parameters

SanitizeNodes

CxList of sanitizer nodes.

Return Value

Returns a CxList which is a subset of paths that doesn't include sanitize nodes.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

The return value may be empty (Count = 0).

Example

```
CxQL  
  
This example demonstrates the CxList.SanitizeCxList () method.  
The input source code is:  
  
public void setString (String input){  
    String otherStr = input;  
    lst.add(otherStr);  
}  
CxList paths = All.DataInfluencingOn(All.FindByShortName("add"));  
CxList sanitizeNodes = All.FindByShortName("input");  
result = paths.SanitizeCxList(sanitizeNodes);  
  
the result would consist of 3 items:  
all ends with add in lst.add(otherStr);  
starts:  
otherStr      (in String otherStr = input;)  
lst           (in lst.add(otherStr);)  
otherStr      (in lst.add(otherStr);)
```

Version Information

Supported from 7.1.2

4.124 CxList.FillGraphsList Method (CxList)

Fills graphs for the list of roots given.

Syntax

```
CxQL  
public void FillGraphsList (CxList graphRoots)
```

Parameters

graphRoots

List of roots to be filled with the graphs.

Return Value

None.

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL  
  
This example demonstrates the CxList.FillGraphsList () method.  
With any Input source code, the method can be called after a Query.  
result=All;  
FillGraphsList(result);  
At this point, the result list is filled with the Graphs.
```

Version Information

Supported from 7.1.2

4.125 CxList.FillGraphsList Method (CSharpGraph)

Fill graphs from one root element.

Syntax

```
CxQL  
public void FillGraphsList (CSharpGraph graphRoot)
```

Parameters

graphRoot

CSharpGraph instance to be filled with Graphs.

Return Value

None.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Example

```
CxQL  
  
This example demonstrates the CxList.FillGraphsList () method.  
With any Input source code, the method can be called after a Query.  
first=All.GetFirstGraph();  
FillGraphsList(first);  
At this point, the first is filled with the Graphs.
```

4.126 CxList.GetIndexOfParameter Method ()

For a single Param or ParamDecl returns the index of the parameter 0 based.

Syntax

```
CxQL  
public int GetIndexOfParameter ()
```

Parameters

Return Value

Integer containing the index of the parameter zero based, or -1 if not a parameter or list empty or contains multiple nodes. Note that the CxList must contain exactly one node, and the node must be of type Param or ParamDecl.

Exceptions

Exception type	Condition

Example

```
CxQL  
  
This example demonstrates the CxList.GetIndexOfParameterMethod() method.  
It prints out to the log the index of each of the parameters.  
result = All.FindByType(typeof(Param));  
foreach (CxList list in result)  
{  
    cxLog.WriteDebugMessage("Parameter index = " + list.  
GetIndexOfParameter());  
}
```

4.127 CxList.FindSQLInjections Method (CxList, CxList, CxList)

Returns flow for SQL Injection from input to db that is not sanitized

Syntax

```
CxQL  
public CxList FindSQLInjections (CxList inputs, CxList db, CxList sanitize)
```

Parameters

inputs

CxList containing input elements

db

CxList containing output elements (eg. database)

sanitize

CxList containing sanitizing elements (cast to integer etc).

Return Value

CxList containing flow of SQL injection from input to output which is not flowing through a sanitizer

Exceptions

Exception type	Condition

Remarks

Actually uses `inputs.InfluencingOnAndNotSanitized(db, sanitize)`.

Example

```
CxQL
```

4.128 CxList.FindXSS Method (CxList, CxList, CxList)

Returns flow for XSS from input to output that is not sanitized

Syntax

```
CxQL  
public CxList FindXSS (CxList inputs, CxList outputs, CxList sanitize)
```

Parameters

inputs

CxList containing input elements

outputs

CxList containing output elements for xss.

sanitize

CxList containing sanitizing elements (cast to integer etc).

Return Value

CxList containing flow of XSS from input to output which is not flowing through a sanitizer

Exceptions

Exception type	Condition

Remarks

Actually uses `inputs.InfluencingOnAndNotSanitized(db, sanitize)`.

Example

```
CXQL
```

4.129 CxList.Clone Method ()

Clones the current (this) CxList

Syntax

```
CxQL  
public CxList Clone ()
```

Parameters

Return Value

CxList containing a clone of the current (this) CxList

Exceptions

Exception type	Condition

Example

```
CxQL  
  
CxList A = All.FindByType(typeof(UnknownReference));  
CxList B = A; //B points to same elements as A  
CxList B = A.Clone(); //B has a copy (clone) of the elements in A
```

4.130 CxList.TryGetCSharpGraph<T> Method () where T : CSharpGraph

Try to extract the DOM object from the first node in 'this' CxList and cast it to type 'T'. Returns null if the CxList is empty, or if the casting fails.

Syntax

```
CxQL  
public CxList TryGetCSharpGraph <T>()
```

Parameters

<T> the type to cast the DOM object to (must inherit from CSharpGraph)

Return Value

The DOM object after casting

Exceptions

Exception type	Condition

Example

```
CxQL  
  
CxList A = All.FindById(10);  
CSharpGraph cs = A.TryGetCSharpGraph<CSharpGraph>();  
// If A contains at least 1 node, cs will contain its DOM object
```

Version Information

Supported from 8.4.0

4.131 CxList.GetQueryParam Method

(string paramName)

Try to get a value for a query parameter using the key paramName. Returns an empty string if the key was not found and on errors.

Syntax

```
CxQL  
public string GetQueryParam(string paramName)
```

Parameters

paramName
The parameter name (key)

Return Value

The value of the received key, or an empty string if the key was not found.

Exceptions

Exception type	Condition

Example

```
CxQL  
  
string val = All.GetQueryParam("Param");  
// If the key "Param" was found in the configuration, than val now holds its  
// value, otherwise, val is an empty string  
if (string.IsNullOrEmpty(val))  
{  
    // Use val  
}
```

Version Information

Supported from 8.4.0

4.132 CxList.GetQueryParam<T> Method (string paramName, T defaultVal = default(T))

Try to get a value for a query parameter using the key paramName and parse the returned string value to type T. Returns defaultVal if the key was not found and on errors.

Syntax

```
CxQL  
public string GetQueryParam<T>(string paramName, T defaultVal = default(T))
```

Parameters

<T>

The type of defaultVal and the returned value

paramName

The parameter name (key)

defaultVal

The value to return on errors

Return Value

The value for the received key parsed to type T, or defaultVal if the key was not found or if the value returned cannot be parsed to type T..

Exceptions

Exception type	Condition

Example

```
CxQL  
  
int val = All.GetQueryParam<int>("Param", 0);  
// If the key "Param" was found in the configuration, then val now holds its  
// value, otherwise, val is 0  
if (val > 0)  
{  
    // Use val  
}
```

Version Information

Supported from 8.4.0

4.133 CxList.FindByFiles Method (CxList source)

Return a subset of 'this' instance, where its DOM objects are on the same file(s) as the DOM objects in the 'source' CxList.

Syntax

```
CxQL  
public CxList FindByFiles(CxList source)
```

Parameters

source

A Cxlist that have DOM objects in the required files.

Return Value

Returns Return a subset of 'this' instance, where its DOM objects are on the same file(s) as the DOM objects in the 'source' CxList..

Exceptions

Exception type	Condition

Example

```
CxQL  
  
CxList a = All.FindByFileName("*method.js*");  
CxList b = All.FindByFileName("*method.json");  
Result = a.FindByFiles(b);  
// Return a subset of 'a' where the objects are of the same file as the  
objects of b.
```

Version Information

Supported from 8.4.0

4.134 CxList.FindRegexMatches Method (CxList comments)

Return a subset of 'this' instance which objects are of type Comment, and are equivalent to objects of type Comment in the comments CxList.

Syntax

```
CxQL  
public CxList FindRegexMatches(CxList comments)
```

Parameters

A CxList of Comment type objects to find matches against the Comment objects in 'this'

Return Value

Return a subset of 'this' instance which objects are of type Comment, and are equivalent to objects of type Comment in the comments CxList..

Exceptions

Exception type	Condition

Example

```
CxQL  
  
// Each time a FindByRegexExt or FindByRegex generate Comment type objects,  
// they are get a different NodeId, even if the represent the same string in the  
// project code.  
  
CxList a = All.FindByRegexExt("http://");  
a.Add(All.FindByRegexExt("https://"));  
CxList b = All.FindByRegexExt("http://"); // The strings that starts with  
// http:// in 'a', now exist in 'b' but with a different NodeId number.  
Result = a. FindRegexMatches(b);  
// Return a subset of 'b' where the objects returned are equivalent to other  
// objects in 'a'.
```

Version Information

Supported from 8.4.0

4.135 CxList.GetAssigner Method (CxList others = null)

For each DOM object in 'this' which is on the left side of an assignment, return the right side of the assignment, which are in the others CxList.

Syntax

```
CxQL  
public CxList GetAssigner(CxList others = null)
```

Parameters

others

CxList containing the right side of the assignment. If null – treat it as if it was All.

Return Value

For each DOM object in 'this' which is on the left side of an assignment, return the right side of the assignment, which are in the others CxList

Exceptions

Exception type	Condition

Example

```
CxQL  
  
The input source code is:  
int a = 0;  
int b = a;  
b = 2;  
int c = b > 1 ? 3 : a;  
CxList a = All.FindByShortName("a");  
CxList b = All.FindByShortName("b");  
CxList c = All.FindByShortName("c");  
  
result = b.GetAssigner();  
// result now holds 'a' in int b = a; and 2 in b = 2;  
result = c.GetAssigner();  
// result now holds 3 and 'a' in int c = b > 1 ? 3 : a;  
result = c.GetAssigner(a);  
// result now holds 'a' in int c = b > 1 ? 3 : a;
```

Version Information

Supported from 8.4.0

4.136 CxList.GetAssignee Method (CxList others = null)

For each DOM object in 'this' which is on the right side of an assignment, return the left side of the assignment, which are in the others CxList.

Syntax

```
CxQL  
public CxList GetAssignee(CxList others = null)
```

Parameters

others

CxList containing the left side of the assignment. If null – treat it as if it was All.

Return Value

For each DOM object in 'this' which is on the right side of an assignment, return the left side of the assignment, which are in the others CxList

Exceptions

Exception type	Condition

Example

```
CxQL  
  
The input source code is:  
int a = 0;  
int b = a;  
b = 2;  
int c = b > 1 ? 3 : a;  
CxList a = All.FindByShortName("a");  
CxList b = All.FindByShortName("b");  
CxList c = All.FindByShortName("c");  
  
result = a.GetAssignee();  
// result now holds 'b' in int b = a; and c in int c = b > 1 ? 3 : a;  
result = a.GetAssignee(b);  
// result now holds 'b' in int b = a;
```

Version Information

Supported from 8.4.0

4.137 CxList Abstract Interpretation

Methods

An abstract value is an instance of a class that implements the “`IAbstractValue`” interface.

The interface “`IAbstractValue`” is implemented by the following classes:

- `AnyAbstractValue`
- `IntegerIntervalAbstractValue`
- `StringAbstractValue`
- `TrueAbstractValue`
- `FalseAbstractValue`
- `NullAbstractValue`
- `ObjectAbstractValue`
- `FunctionAbstractValue`
- `NoneAbstractValue`

The `ObjectAbstractValue` class has two parameters which can be used to query a certain object:

- **ParentPointerMayBeNull**: indicated that the pointer's / instance's possible values contain the null value)
- **AllocationState**: current allocation state in the heap, value may be one the following:
 - `ObjectAllocationState.Allocated` (object is allocated and exists in the heap)
 - `ObjectAllocationState.Released` (object has been freed / released from the heap)
 - `ObjectAllocationState.Ambiguous` (object either exists or has been released from the heap)

`bool IAbstractValue.IncludedIn(IAbstractValue absValue, bool strictTypeMatch = false)`

Parameters

abstractValue

An abstract value

strictTypeMatch

Return Value

If “this” includes the abstract value parameter “`absValue`” → “`IncludedIn`” method returns true, otherwise method returns false.

Examples:

Here is a list of `IAbstractValue`

```
List<IAbstractValue> list = {new AnyAbstractValue(),
                           new IntegerIntervalAbstractValue(1, 2),
                           new StringAbstractValue("body")};
```

1. `int count = 0;`
`IAbstractValue source = new IntegerAbstractValue(1);`
`foreach (var val in list)`
 `if (source.IncludedIn(val)) count++;`
The value of variable `count` will be 2. // any and integer return “true”
2. `int count = 0;`
`IAbstractValue source = new IntegerAbstractValue(1);`

```
foreach (var val in list)
    if (source.IncludedIn(val,true)) count++;
```

The value of variable count will be 1. // only integer return "true"

```
3. int count = 0;
   IAbstractvalue source = new IntegerAbstractvalue(1);
   foreach (var val in list)
       if (val.IncludedIn(source)) count++;
```

The value of variable count will be 0. // [1,2] not included in [1,1]. Here is the question (IncludeIn) activate with opposite order.

4.137.1 CxList.FindByAbstractValue Method (Func<IAbstractValue, bool> criterion)

Returns a CxList which is a subset of this instance whose elements have an abstract value that fulfills the criterion.

Syntax

```
CxQL  
public CxList FindByAbstractValue (Func<IAbstractValue, bool> criterion)
```

Parameters

criterion

Lambda method that can filter required items from this CxList according to their abstract value. This function have one parameter of type IAbstractValue and returns bool.

Return Value

A subset of this instance whose elements have match the requested creterion.

Exceptions

Exception type	Condition

Example 1

```
CxQL  
  
Find all DOM elements whose abstract value is an integer inside the interval [0,10]  
IAbstractValue intervalZeroToTen = new IntegerIntervalAbstractValue(0,10);  
CxList res = All.FindByAbstractValue(abstractvalue =>  
    abstractvalue.IncludedIn(intervalZeroToTen,true));  
  
Find all DOM elements for which the integer 0 in inside their abstract value  
IAbstractValue zero = new IntegerIntervalAbstractValue(0);  
CxList res = All.FindByAbstractValue(abstractvalue =>  
    zero.IncludedIn(abstractvalue));  
  
Find all DOM elements whose abstract value has a given type  
CxList res = All.FindByAbstractValue(abstractvalue =>  
    abstractvalue is StringAbstractValue);
```

Example 2

```
CxQL

The input source code is:
int counter = 0;
int x = counter + 5;
string str = "a";
string secondStr = str + "b";
CxList a = All. FindByAbstractValue(abstractValue =>
    abstractValue is IntegerIntervalAbstractValue);
CxList b = All. FindByAbstractValue (abstractValue =>
    abstractValue is StringAbstractValue);

result = a;
// result now holds 0, '+', 'counter' and 5 in
int counter = 0;
int x = counter + 5;
result = b;
// result now holds "a", '+', 'str' and "b" in
string str = "a";
string secondStr = str + "b";
```

Example 3

```
CxQL

The input source code is:
var y;
int counter = 0;
int x = counter + 5;
y();
IAbstractValue zeroAbsValue = new IntegerIntervalAbstractValue(0);
result = All. FindByAbstractValue(abstractValue =>
    zeroAbsValue.IncludedIn(abstractValue));
/* result now holds 0 and 'counter' in
   int x = counter + 5;
   And also contains y in: (because y has AnyAbstractValue which includes 0)
   y();
*/

result = All. FindIncludedAbstractValue(abstractValue =>
    zeroAbsValue.IncludedIn(abstractValue,true));
// result now holds 0 and 'counter' in
int x = counter + 5;
// it does not contain y because we asked for strictTypeMatch
```

Example 4

CxQL

The input source code is:

```
int counter = 0;
int x = counter + 5;
function foo() {} // void method
foo();
```

```
IAbstractValue zeroToFiveAbsValue = new IntegerIntervalAbstractValue(0,5);
```

```
result = All. FindIncludedInAbstractValue(abstractValue =>
    abstractValue.IncludedIn(zeroToFiveAbsValue));
```

```
/* result now holds 0, 5, 'counter' and the sum (counter + 5) in
```

```
int counter = 0;
int x = counter + 5;
And also contains foo in:
```

```
foo (); // because y has AnyAbstractValue which includes [0,5]
*/
```

```
result = All. FindIncludedInAbstractValue(abstractValue =>
    abstractValue.IncludedIn(zeroToFiveAbsValue, true));
```

```
// result now holds 0, 5, 'counter' and the sum of (counter + 5) in
```

```
int x = counter + 5;
// it does not contain foo because we asked for strictTypeMatch
```

Version Information

Supported from 8.6.0

4.137.2 CxList.FindByAbstractValues Method (CxList sources)

Returns a CxList which is a subset of this instance whose elements have an abstract value equal to the abstract value of one element in the sources CxList.

Syntax

```
CxQL  
public CxList FindByAbstractValues(CxList sources)
```

Parameters

sources
A CxList.

Return Value

A subset of this instance whose elements have an abstract value equal to the abstract value of one element in the sources CxList.

Exceptions

Exception type	Condition

Example

```
CxQL  
  
The input source code is:  
string str = "a";  
string secondStr = str + "b";  
result = All.FindByAbstractValues(All.FindByType(typeof(StringLiteral)));  
// result now holds "a", 'str' and "b" in  
string str = "a";  
string secondStr = str + "b";
```

Version Information

Supported from 8.4.2

4.138 Scan Provider Methods

4.138.1 cxScan.IsFrameworkActive Method (string frameworkName)

Returns bool if requested framework present in scanned project..

Syntax

```
CxQL
public bool IsFrameworkActive (string frameworkName)
```

Parameters

string
Name of requested framework

Return Value

True → requested framework present in this project.
False → otherwise

Exceptions

Exception type	Condition

Example

```
CxQL
Implementation of query JavaScript Kony_Code_Injection

if(cxScan.IsFrameworkActive("Kony"))
{
    CxList inputs = Kony_UI_Inputs();
    CxList Eval = Find_Outputs_CodeInjection();
    CxList sanitize = Code_Injection_Sanitize();
    and etc.
}

if "Kony" framework present →this query do something, otherwise do nothing
You can test existing of every framework.
```

Version Information

Supported from 8.6.0

4.138.2 cxScan.GetScanProperty Method (string key)

Returns string with a value of requested property..

Syntax

```
CxQL  
public string GetScanProperty (string key)
```

Parameters

string

Name of requested property, currently only `projectPath` property supported.

Return Value

If requested property exists → value of requested property will be returned.

Otherwise empty string will be returned.

Exceptions

Exception type	Condition

Example

```
CxQL  
  
string projectPath = cxScan.GetScanProperty("projectPath");  
string projectPath contains value of "projectPath" property.
```

Version Information

Supported from 8.6.0

4.139 CxList CxXPath Methods

4.139.1 IEnumerable<CxXmlDoc> GetXmlFiles Method (string filter, bool IgnoreNamespaces = false)

Returns an enumerated list of XML files filtered according to the first parameter.

Syntax

```
CxQL
public IEnumerable<CxXmlDoc> GetXmlFiles (string filter, bool
IgnoreNamespaces = false)
```

Parameters

string

File extension pattern to be used as filter.

bool

Specifies whether the search should ignore the namespaces. This field is not required and its default value is false.

Return Value

Returns an enumerated list of XML files.

Exceptions

Exception type	Condition

Example

```
CxQL

IEnumerable xmlDoc = All.GetXmlFiles("*.cx", true);

Returns an enumerated list of XML files filtered by "*.cx"
```

Version Information

Supported from 8.6.0

4.139.2 CxList CreateXmlNode Method (XPathNavigator input, CxXmlDoc xmlDoc, int language, bool save, int depth = 1)

Return a CxList composed by CxXmlNode.

Syntax

```
CxQL
public CxList CreateXmlNode(XPathNavigator input, CxXmlDoc xmlDoc, int
language, bool save, int depth = 1)
```

Parameters

- XPathNavigator**
Provides a cursor model for navigating XML data.
- CxXmlDoc**
Document where the node will be created.
- int**
Id of the language.
- bool**
Specifies if the node should be saved.
- int**
Depth of search. Default value is 1.

Return Value

Return a CxList with CxXmlNodes for the given XPath.

Exceptions

Exception type	Condition

Example

```
CxQL

// create an XPathDocument object
XPathDocument xmlPathDoc = new XPathDocument(xmlFileName);

// create a navigator for the xpath doc
XPathNavigator xNav = xmlPathDoc.CreateNavigator();

result = All.CreateXmlNode(xNav, xmlDoc, 1, false, 1);

Returns a CxList of nodes in a given CxXmlDoc.
```

Version Information

Supported from 8.6.0

4.139.3 CxList FindXmlNodesByQualifiedName Method (string xmlFilterFiles, int language, string prefix, string nodeName, bool includeAttributes, string attributeName = "", string attributeValue = "", bool usesRegex = false, bool ignoreCase = false)

Return a CxList with CxXmlNode elements following the values defined by the parameters.

Syntax

```
CxQL  
public CxList FindXmlNodesByQualifiedName(string xmlFilterFiles, int  
language, string prefix, string nodeName, bool includeAttributes, string  
attributeName "", string attributeValue = "", bool usesRegex = false, bool  
ignoreCase = false)
```

Parameters

- string
File extension pattern to be used as filter.
- int
Id of the language.
- string
The name of the prefix.
- string
The name of the node.
- bool
Specifies if the search should include attributes. This field is not required and its default value is false.
- string
The name of the attribute. This field is not required.
- string
The value of the attribute. This field is not required.
- bool
Specifies if the search should use regex. This field is not required and its default value is false.
- bool
Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

```
CxQL  
The input source code is:
```

```
<aura:attribute name="href" type="String" default="null"/>  
  
result = All.FindXmlNodesByQualifiedNames("*Test.app", 8, "aura", "type");  
// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.4 CxList FindXmlNodesByQualifiedNameAndValue Method (string xmlFilterFiles, int language, string prefix, string nodeName, string nodeValue, bool usesRegexForNodeValue = false, bool ignoreCase = false)

Returns a CxList with CxXmlNode elements that contain the same name and value defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlNodesByQualifiedNameAndValue(string xmlFilterFiles, int
language, string prefix, string nodeName, string nodeValue, bool
usesRegexForNodeValue = false, bool ignoreCase = false)
```

Parameters

string

File extension pattern to be used as filter.

int

Id of the language.

string

The name of the prefix.

string

The name of the node.

string

The value of the node.

bool

Specifies if the search should use regex for the node value. This field is not required and its default value is false.

bool

Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

CxQL

The input source code is:

```
<aura:attribute name="href" type="String" default="null">
  {!userManager.isAuthorized}
</aura:attribute/>
```

```
result = All.FindXmlNodesByQualified_name_and_value("*Test.app", 8, "aura",  
"attribute", "userManager.isAuthorized");  
  
// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.5 CxList FindXmlNodesByLocalName Method (string xmlFilterFiles, int language, string nodeName, bool includeAttributes = false, string attributeName = "", string attributeValue = "", bool usesRegex = false, bool ignoreCase = false)

Returns a CxList with CxXmlNode elements that contain the same local name defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlNodesByLocalName(string xmlFilterFiles, int language,
string nodeName, bool includeAttributes = false, string attributeName = "",
string attributeValue = "", bool usesRegex = false, bool ignoreCase = false)
```

Parameters

- string
File extension pattern to be used as filter.
- int
Id of the language.
- string
The name of the node.
- bool
Specifies whether the search includes the attributes. This field is not required and its default value is false.
- string
The name of the attribute. This field is not required.
- string
The value of the attribute. This field is not required.
- bool
Specifies if the search should use regex. This field is not required and its default value is false.
- bool
Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

CxQL

```
The input source code is:
<a href="{!obj.href}">click me</a>
```

```
result = All.FindXmlNodesByLocalName("*.cmp", 8, "a", true, "href",  
"[{}[!][^}]+{}]", true, true);  
  
// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.6 CxList FindXmlNodesByLocalNameAndValue Method (string xmlFilterFiles, int language, string nodeName, string nodeValue, bool usesRegexForNodeValue = false, bool ignoreCase = false)

Returns a CxList with CxXmlNode elements that contain the same local name and value defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlNodesByLocalNameAndValue(string xmlFilterFiles, int
language, string nodeName, string nodeValue, bool usesRegexForNodeValue =
false, bool ignoreCase = false)
```

Parameters

string

File extension pattern to be used as filter.

int

Id of the language.

string

The name of the node.

string

The value of the node.

bool

Specifies if the search should use regex for the node value. This field is not required and its default value is false.

bool

Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Returns a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

```
CxQL

The input source code is:
<a href="{!obj.href}">click me</a>

result = All. FindXmlNodesByLocalNameAndValue("*.cmp", 8, "a", "click me",
true, "href", "[{}[!][^]]+{}", true, true);

// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.7 CxList FindXmlAttributesByName Method (string xmlFilterFiles, int language, string attributeName, bool ignoreCase = false)

Returns a CxList with CxXmlNode elements that contain attributes with the same name defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlAttributesByName(string xmlFilterFiles, int language,
string attributeName, bool ignoreCase = false )
```

Parameters

string

File extension pattern to be used as filter.

int

Id of the language.

string

The name of the attribute.

bool

Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

```
CxQL
The input source code is:
<div id="error-section"></div>

result = All. FindXmlAttributesByName("*.app", 8, "id", true);

// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.8 CxList FindXmlAttributesByValue Method (string xmlFilterFiles, int language, string attributeValue, bool usesRegex = false)

Returns a CxList with CxXmlNode elements that contain attributes with the same value defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlAttributesByValue(string xmlFilterFiles, int language,
string attributeValue, bool usesRegex = false)
```

Parameters

string
File extension pattern to be used as filter.

int
Id of the language.

string
The value of the attribute.

bool
Specifies if the search should use regex.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

```
CxQL
The input source code is:
<div id="error-section"></div>

result = All. FindXmlAttributesByValue("*.app", 8, "error-section", false);

// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.9 CxList FindXmlAttributesByNameAndValue Method (string xmlFilterFiles, int language, string attributeName, string attributeValue, bool usesRegex = false, bool ignoreCase = false)

Returns a CxList with CxXmlNode elements that contain attributes with the same name and value defined in the parameters.

Syntax

```
CxQL
public CxList FindXmlAttributesByNameAndValue(string xmlFilterFiles, int
language, string attributeName, string attributeValue, bool usesRegex =
false, bool ignoreCase = false)
```

Parameters

string

File extension pattern to be used as filter.

int

Id of the language.

string

The name of the attribute.

string

The value of the attribute.

bool

Specifies if the search should use regex.

bool

Specifies if the search should be case sensitive. This field is not required and its default value is false.

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition

Example

```
CxQL
```

```
The input source code is:
```

```
<div id="error-section"></div>
```

```
result = All.FindXmlAttributesByNameAndValue("*.app", 8, "id", "error-  
section", false, true);
```

```
// Result now holds the entire tag block
```

Version Information

Supported from 8.6.0

4.139.10 Void AddSupportForExpressionLanguageForFramework (string framework)

Sets the support for expression language for the framework to true. Must be done at least once in a scan before running cxxPath queries for expression language.

Syntax

```
CxQL  
public void AddSupportForExpressionLanguageForFramework (string framework)
```

Parameters

string
The name of the framework

Exceptions

Exception type	Condition

Example

```
CxQL  
  
The input source code is:  
<aura:component >  
  <aura:attribute name="src" type="String"  
  default="javascript:alert(document.cookie)"/>  
  Attribute test in CSP  
mode (LEX)  
  <iframe src="{!v.src}"></iframe>  
</aura:component>  
  
  cxXPath.AddSupportForExpressionLanguageForFramework("Lightning");  
  // will set the support of the lightning expression language to true
```

Version Information

Supported from 8.9.0

4.139.11 public CxList FindAllAttributesThatHoldExpressions(string xmlFilterFiles, int language, string framework)

Returns a CxList with CxXmlNode elements that contain nodes that have hold expressions as an attribute value.

Syntax

```
public CxList FindAllAttributesThatHoldExpressions(string xmlFilterFiles,  
int language, string framework)
```

Parameters

string
File extension pattern to be used as filter.

int
Id of the language.

string
The name of the framework

Return Value

Return a CxList with CxXmlNode elements.

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL  
  
<ui:button label="Get custom objects" press="{!c.get_objs}"/>  
result=cxXPath.FindAllAttributesThatHoldExpressions("*.cmp", 8,  
"Lightning");  
// Result now holds the attribute which value is an expression ("press"  
CxXml node)
```

Version Information

Supported from 8.9.0

4.139.12 public CxList GetTextNodesExpressions(string xmlFilterFiles, string framework, int language)

Returns a CxList with all the expressions that are located in XML text for a given framework

Syntax

```
public CxList GetTextNodesExpressions(string xmlFilterFiles, string framework, int language)
```

Parameters

string
File extension pattern to be used as filter.

string
The name of the framework

int
Id of the language.

Return Value

A CxList which contains expressions that are located inside the XML text

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL  
  
<p><a href="{!obj.Phone}">Phone of {!obj.Name}</a></p>  
  
result = cxXPath.GetTextNodesExpressions("*.cmp", "Lightning", 8);  
  
// Result now holds the Member Access of "Name"
```

Version Information

Supported from 8.9.0

4.139.13 public CxList createAttributesDefinition(string xmlFilterFiles, int language, string framework)

Returns a CxList with elements that will represent a Declarators of a framework specific variable definitions.

Syntax

```
public CxList createAttributesDefinition(string xmlFilterFiles, int language, string framework)
```

Parameters

string
File extension pattern to be used as filter.

int
Id of the language.

string
The name of the framework

Return Value

A CxList which contains a set of Declarators that are specific for a given framework

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CXQL  
  
<aura:attribute name="accounts" type="Account[]"/>  
  
result=cxXPath.createAttributesDefinition("*.cmp", 8, "Lightning");  
  
// Result now holds Declarator of a variable of name "accounts" of type  
"Account[]" and of private accessibility
```

Version Information

Supported from 8.9.0

4.139.14 public CxList GetXMLNodeDescendents(CxList originNodes, CxList descendentExpressionGroup)

Returns a CxList which is a subset of descendentExpressionGroup and is a XML DOM descendent of CxXML originNodes

Syntax

```
public CxList GetXMLNodeDescendents(CxList originNodes, CxList
descendentExpressionGroup)
```

Parameters

CxList

A list of CxXML elements which would serve as the scope to look under

CxList

A list of Expressions from which the Descendants will be extracted

Return Value

A CxList which is a subset of descendentExpressionGroup and is a XML DOM descendent of CxXML originNodes

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL

<aura:iteration var="obj" items="{!v.saccounts}">
  <p>
<a href="{!obj.Name}">{!'Name of ' + obj.Name}</a></p>
  <p><a href="{!obj.Phone}">Phone of {!obj.Name}</a></p>
</aura:iteration>

CxList iteration = cxXPath.CreateIterationVarDefinition("*.*cmp", 8,
"Lightning");
CxList elementOfDeclarator =
cxXPath.GetElementOfCreatedDeclaration(iteration);
CxList desc = cxXPath.GetXMLNodeDescendents(elementOfDeclarator,
allExpressionsInProject);

// Assuming that allExpressionsInProject will hold all expressions in the
framework, result will contain the expressions for obj.Name MemberAccesses ,
obj.Phone MemberAccesses and a binaryExpression (in total 4 CxList results)
```

Version Information

Supported from 8.9.0

4.139.15 public CxList GetAllExpressionDescendents(CxList descendentExpressionGroup, int language)

Returns a CxList which is all descendants of the the descendentExpressionGroup

Syntax

```
public CxList GetAllExpressionDescendents(CxList descendentExpressionGroup,  
int language)
```

Parameters

CxList

The Ancestors whose descendants are to be returned

int

Id of the language.

Return Value

Returns all elements that descends any of the elements in the descendentExpressionGroup parameter

Exceptions

Exception type	Condition

Example

```
CXQL  
  
<iframe src="{!'https:' + v.frameSrc}">iframe</iframe>  
  
CxList attr=cxXPath.FindAllAttributesThatHoldExpressions("*.cmp", 8,  
"Lightning");  
CxList expr=cxXPath.GetExpressionsByAttributes(attr);  
result=cxXPath.GetAllExpressionDescendents(expr,8);  
// will return 4 results (binaryExpr, StringLiteral, MemberAccess,  
UnknownReference).
```

Version Information

Supported from 8.9.0

4.139.16 public CxList GetElementOfCreatedDeclaration(CxList declarations)

Returns a CxList with CxXmlNode elements that are DOM related to framework created Declarators

Syntax

```
public CxList GetElementOfCreatedDeclaration(CxList declarations)
```

Parameters

CxList

A list of XML framework related Declarators

Return Value

A CxList with CxXmlNode elements that are DOM related to framework created Declarators

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CXQL  
  
    <aura:attribute name="Id" type="String" access="Private" default="nil"/>  
  
CxList declarators=cxXPath.createAttributesDefinition("*.cmp", 8,  
"Lightning");  
result=cxXPath.GetElementOfCreatedDeclaration(declarators);  
  
// result will contain "attribute" CxXmlNode element
```

Version Information

Supported from 8.9.0

4.139.17 public CxList GetAttributeByExpression(CxList expression)

Returns a CxList with CxXmlNode attributes that are DOM related (key of expression) to the expressions given as a parameter

Syntax

```
public CxList GetAttributeByExpression(CxList expression)
```

Parameters

CxList

A list of expressions that appear as a value to an XML attribute

Return Value

A CxList with CxXmlNode attributes that are DOM related (key of expression) to the expressions given as a parameter

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL
<iframe src="{!v.src}"></iframe>

CxList AllAttributesThatHoldExpressions =
cxXPath.FindAllAttributesThatHoldExpressions("*.cmp", 8, "Lightning");
CxList expression =
cxXPath.GetExpressionsByAttributes(AllAttributesThatHoldExpressions);
result = cxXPath.GetAttributeByExpression(expression);

// result will contain one CXML node for "src" attribute
```

Version Information

Supported from 8.9.0

4.139.18 public CxList GetExpressionsByAttributes(CxList attributes)

Returns a CxList of expressions that are DOM related to the attributes parsed as param (given a key of attributes will return a set of expressions that are their values).

Syntax

```
public CxList GetExpressionsByAttributes(CxList attributes)
```

Parameters

CxList

A list of attributes that have an expression as a value

Return Value

A CxList of expressions that are DOM related to the attributes parsed as param

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CxQL
<iframe src="{!v.src}"></iframe>

CxList AllAttributesThatHoldExpressions =
cxXPath.FindAllAttributesThatHoldExpressions("*.cmp", 8, "Lightning");
Result=
cxXPath.GetExpressionsByAttributes(AllAttributesThatHoldExpressions);

// result will return a MemberAccess "src"
```

Version Information

Supported from 8.9.0

4.139.19 public CxList GetElementByExpression(CxList expressions)

Returns a CxList of CxXmlNode that hold the element that is DOM related to a given expression.

Syntax

```
public CxList GetElementByExpression(CxList expressions)
```

Parameters

CxList

A list of expressions

Return Value

A CxList of CxXmlNode that hold the element that is DOM related to a given expression

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

CXQL

```
<iframe src="{!v.src}"></iframe>
```

```
CxList AllAttributesThatHoldExpressions =  
cxXPath.FindAllAttributesThatHoldExpressions("*.cmp", 8, "Lightning");  
CxList exp=  
cxXPath.GetExpressionsByAttributes(AllAttributesThatHoldExpressions);  
result= cxXPath.GetElementByExpression(exp);
```

```
// result will contain the CxXmlNode for iframe element.
```

Version Information

Supported from 8.9.0

4.139.20 public CxList CreateIterationVarDefinition(string xmlFilterFiles, int language, string framework)

Returns a CxList with elements that will represent a Declarators of a framework specific iteration statement.

Syntax

```
public CxList CreateIterationVarDefinition(string xmlFilterFiles, int language, string framework)
```

Parameters

string
File extension pattern to be used as filter.

int
Id of the language.

string
The name of the framework

Return Value

A CxList which contains a set of Declarators that are specific for a given framework

Exceptions

Exception type	Condition
NullReferenceException	parameter is a null reference

Example

```
CXQL  
  
<aura:iteration var="obj" items="{!v.customobjects}">  
  
result=cxXPath.CreateIterationVarDefinition ("*.cmp", 8, "Lightning");  
  
// Result now holds Declarator of a variable of name "obj" of type relevant  
to customobjects and of private accessibility
```

Version Information

Supported from 8.9.0

5 Method Documentation (for internal use only)

5.1 CxList.SetQueryProperty Method (QueryProperties.propertyEnum, QueryProperties.flowDirectionEnum)

Adds/modifies a query property of the current query

Syntax

```
CxQL  
public static void SetQueryProperty (QueryProperties.propertyEnum  
queryProperty, QueryProperties.flowDirectionEnum directionValue)
```

Parameters

queryProperty

enum of query properties: FLOW_DIRECTION

directionValue

enum of flow direction: From_Small_To_Large = 1, From_Large_To_Small,
From_Start, From_End

Exceptions

Exception type	Condition

Example

```
CxQL  
  
SetQueryProperty(QueryProperties.propertyEnum.FLOW_DIRECTION,  
QueryProperties.flowDirectionEnum.From_Start); //makes the calculation of  
flows be from start node to end node.
```

Version Information

Supported from 8.0.0

5.2 CxList.GetSanitizerByMethodInCondition n Method (CxList)

For each input method, finds all the calls inside a "if" condition and returns all the references, of the methods parameters, that are inside the "if" statement.

Syntax

```
CxQL  
public CxList GetSanitizerByMethodInCondition(CxList MethodCallsInCondition)
```

Parameters

MethodCallsInCondition

method call list inside "if" condition (must be of type MethodInvoke)

Return Value

all references of a method call parameter in the scope of the if statement

Example

This example demonstrates the `CxList.GetSanitizerByMethodInCondition(CxList MethodCallsInCondition)` method.

The input source code is:

```
String a = getInput();  
if(Valid(a)){  
    Print(a);  
}
```

```
CxList valid = All.FindByShortName("Valid");  
result = All.GetSanitizerByMethodInCondition(valid);
```

the result would consist of 1 item:

```
a      (in Print(a))
```

The purpose of the query is to mark 'a' as a sanitizer, because the flow doesn't pass through the condition.

Remarks

Calls `GetSanitizerByMethodInCondition(MethodCallsInCondition, IfBlock.Both)`.

Version Information

Supported from 7.1.2

5.3 CxList.GetSanitizerByMethodInCondition n Method (CxList, IfBlock)

For each method, finds all the calls inside a "if" condition and returns all the references, of the methods parameters, that are inside the "if" block (the IfBlock input parameter) statement.

Syntax

```
CxQL  
public CxList GetSanitizerByMethodInCondition(CxList MethodCallsInCondition,  
IfBlock block)
```

Parameters

MethodCallsInCondition

method call list inside "if" condition (must be of type MethodInvoke)

block

select only "true", only "false" or both scopes.

Return Value

all references of a method call parameter in the scope of the if statement

Example

This example demonstrates the `CxList.GetSanitizerByMethodInCondition(CxList MethodCallsInCondition, IfBlock block)` method.

The input source code is:

```
String a = getInput();  
if(Valid(a)){  
    Print(a);  
}
```

```
CxList valid = All.FindByShortName("Valid");  
result = All.GetSanitizerByMethodInCondition(valid,CxList.IfBlock.True);
```

the result would consist of 1 item:

```
    a      (in Print(a))
```

The purpose of the query is to mark 'a' as a sanitizer, because the flow doesn't pass through the condition.

Version Information

Supported from 7.1.2

6 CxList Operators

The operators of the **CxList** class are listed here.

Public Operators

== Operator	Determines whether two specified CxList objects have the same values.
!= Operator	Determines whether two specified CxList objects do not have the same values (they differ by a least one value).
+ Operator	Merges two specified CxList objects (same as operator)
- Operator	Removes the values of second specified CxList object from the first one.
& Operators	Intersects the values of the two specified CxList objects (same as * operator)
Operator	Merges two specified CxList object (same as + operator)
* Operator	Intersects the values of the two specified CxList objects (same as & operator)
< Operator	Return true if the first specified CxList is completely contained within the second one.
> Operator	Return true if the second specified CxList is completely contained within the first one.
<= Operator	Return true if the first specified CxList is completely contained within the second one or they are equal.
=> Operator	Return true if the second specified CxList is completely contained within the first one or they are equal.

7 CxQuery Miscellaneous Methods

7.1 cxLog.WriteDebugMessage Method (string)

Display string to DebugMessages tab in CxAudit program

Syntax

```
CxQL  
public void cxLog.WriteDebugMessage(string str)
```

Parameters

String to be displayed.

Return Value

none.

Exceptions

Exception type	Condition
ArgumentNullException	parameter is a null reference

Remarks

All calling to cxLog.WriteDebugMessage should be removed from production version!!!

It also prints the debug message into the CxSAST log file (even outside CxAudit).

Example

The following code example shows how you can use the cxLog.WriteDebugMessage method.

```
CxQL  
  
This example demonstrates the cxLog.WriteDebugMessage method.  
The input source code is:  
class c11  
{  
    void foo()  
    {  
        int a = 3;  
        int b = 5;  
    }  
}  
result = All.FindByShortName("foo");  
if (result.Count > 0)  
    cxLog.WriteDebugMessage(result.GetFirstGraph().ShortName);  
    cxLog.WriteDebugMessage ("number of DOM elements =" + All.Count);  
  
the result would be - on DebugMessage tab in CxAudit program  
foo  
number of DOM elements = 14
```

Version Information

Supported from v1.8.1

8 Appendix A. CxDOM Types

The built-in types in CxDOM are listed here:

Types	Types (cont.)	Types(Cont.)
AccessorDecl	DelegateInvokeExpr	OperatorDecl
AccessorModifiers	DestructorDecl	OverloadableOperator
ArgumentRef	DictionaryCreateExpr	Param
ArrayCreateExpr	DictionaryInitializer	ParamDecl
ArrayElementRef	EnumDecl	ParamDirection
ArrayInitializer	EnumMemberDecl	PointerTypeRef
AssemblyReference	EventDecl	PostfixExpr
AssignExpr	EventRef	PostfixOperator
AssignOperator	ExprStmt	PropertyDecl
AssociativeArrayExpr	FieldDecl	PropertyRef
AssociativeArrayPropertyEntry	FieldRef	PropertySetValueRef
AssociativeArrayRegularEntry	ForEachStmt	RankSpecifier
AttachDelegateStmt	FunctionTypeRef	RealLiteral
AttributeTarget	GenericsConstraints	RemoveDelegateStmt
BaseRef	GenericTypeRef	ReturnStmt
BinaryExpr	GotoStmt	SliceExpression
BinaryOperator	GraphTypes	StringLiteral
BooleanLiteral	IfStmt	StructDecl
BreakStmt	Import	SubExpr
BuiltInType	IndexerDecl	SwitchStmt
Case	IndexerRef	TernaryExpr
CastExpr	IntegerLiteral	ThisRef
Catch	InterfaceDecl	ThrowStmt
CharLiteral	IterationStmt	TryCatchFinallyStmt
CheckedStmt	IterationType	TupleCreateExpr
ClassDecl	LabeledStmt	TupleInitializer
CodeCollectionAttribute	LambdaExpr	TypeKind
CodeElementAttribute	LinePragma	TypeModifiers
Comment	LocalRef	TypeOfExpr
CommentStmt	LockStmt	TypeRef
ConstantDecl	MemberAccess	UnaryExpr

Types	Types (cont.)	Types(Cont.)
ConstantDeclStmt	MemberKind	UnaryOperator
ConstructorDecl	MethodDecl	UncheckedStmt
ContinueStmt	MethodInvokeExpr	UnknownReference
CreateDelegateExpr	MethodRef	UsingStmt
CustomAttribute	Modifiers	VariableDecl
CxXmlNode	NamespaceDecl	VariableDeclStmt
Declarator	NullLiteral	
DelegateDecl	ObjectCreateExpr	

Example

In order to better understand each of these types, try the following query:

CxQL

```
result = All.FindByType(typeof(IfStmt));  
"IfStmt" is one of the above types.
```
